Lecture - 11
Linear Transformation Part – 1

(Refer Slide Time: 00:35)

This lecture includes the definition, will give some examples of linear transformation. Then, we will discuss some important results regarding this. And then I will introduce the concept of rank and nullity. And finally, some results related to rank and nullity.

(Refer Slide Time: 00:50)

Definition
Let V and W be Real vector spaces. A linear transformation T from V into W is a function ($T: V \rightarrow W$) which assigns a unique vector $T(\alpha)$ in W for each α in V such that

i) T is additive
 $T(\alpha + \beta) = T(\alpha) + T(\beta)$ for each α, β in V

ii) T is homogeneous
 $T(c\alpha) = cT(\alpha)$ for every scalar c in R

The Principle of Superposition
 $T(a\alpha + b\beta) = aT(\alpha) + bT(\beta)$ for α, β in V and scalars a, b in R

To start with I will first give the definition of linear transformation. For this, let us consider two real vector spaces V and W . And a linear transformation T from V into W is a function. I say T is from V to W , which assigns a unique vector $T\alpha$ in W for each α in V , such that it satisfies the properties. The first property is that T is additive. By this I mean to say, that when T operated on α plus β , for each α and β in V . Then, it will become transform to $T\alpha$ plus $T\beta$. By this, we say that T is additive.

The second property is T is homogeneous. By this I mean to say, that when T is applied on $c\alpha$, α is the vector. And c is the scalar in R , then it becomes c times $T\alpha$. So, $Tc\alpha$ is equal to $cT\alpha$. And if these two properties are satisfied, then such a transformation T is called a linear transformation. I will introduce the principle of superposition. By this I am mean to say, that if I have two vectors α β in V . Then T of $a\alpha$ plus $b\beta$ is equal to a of $T\alpha$ plus b of $T\beta$, where a and b are scalar in R .

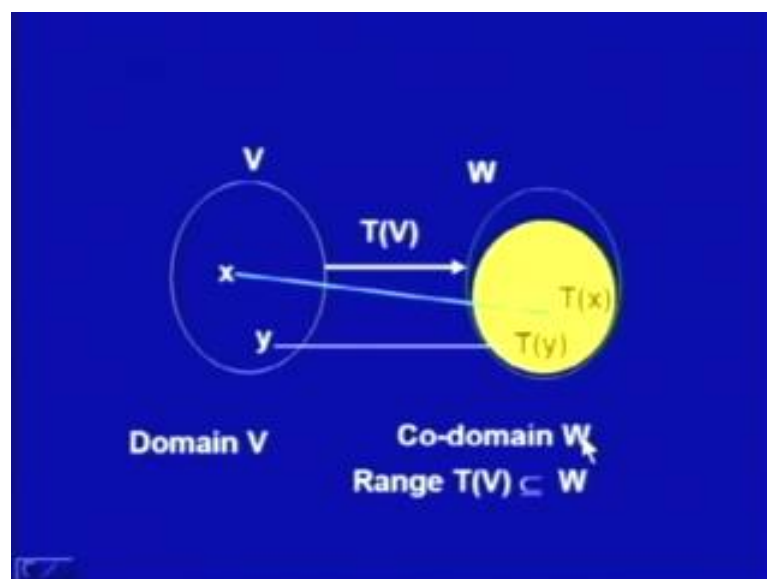

(Refer Slide Time: 02:31)

$T : V \rightarrow W$ as a mapping such that
 $T(c\alpha + \beta) = cT(\alpha) + T(\beta)$ for α, β in V

A linear transformation from $V \rightarrow V$ is also called a linear operator on V .

The way I have define this transformation, I can say that T from V into W is a mapping. Such that, T of c alpha plus beta is equal to c time T alpha plus T beta, for alpha beta in V . In fact, this will become an alternative definition for linear transformation. So, instead of satisfying two properties, linear properties and homogeneous property. The two properties are combine into one single property, defined in this manner. Now, a linear transformation from V to V is also called a linear operator on V .

(Refer Slide Time: 03:17)

To illustrate what I have done, let us consider two vector space V and W . By this I am mean to say, V consist of a set of vectors two operators, one is addition of vectors, another scalar multiplication define in V as well as in W . And they satisfy certain properties. So, that way V and W are two vector spaces. Then, a linear transformation from V into W is denoted by T V provided a vector in x goes to $T x$ in W . And a vector in y goes to $T y$ in W .

And they satisfied the property the homogeneous property and the linear property, which I have defined earlier. Now, in this case I say V is the domain of the linear transformation, while W is co-domain for the transformation. The set, which consist of images of x and y in V , all x and y in V . That set is called range of $T V$. And definitely this is a subset of W . Later on, we will prove that it may be a vector space.

(Refer Slide Time: 04:44)

Example 1: Let $T : \mathbb{R}^3 \rightarrow \mathbb{R}^2$ be defined by

$$T \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{bmatrix} x \\ z \end{bmatrix}$$

show that T is a linear transformation.

Solution:

i) T is additive

$$T(\alpha + \beta) = T(\alpha) + T(\beta) \quad \text{for each } \alpha, \beta \text{ in } V$$

$$T \left(\begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} + \begin{pmatrix} x_2 \\ y_2 \\ z_2 \end{pmatrix} \right) = T \begin{pmatrix} x_1 + x_2 \\ y_1 + y_2 \\ z_1 + z_2 \end{pmatrix} = \begin{bmatrix} x_1 + x_2 \\ z_1 + z_2 \end{bmatrix}$$

Now, let us take an example we have a transformation T from \mathbb{R}^3 to \mathbb{R}^2 , which is defined as T of $x y z$ a vector goes to $x z$ in \mathbb{R}^2 . So, this is a vector in \mathbb{R}^3 . And this is a vector in \mathbb{R}^2 . If we define this transformation in this particular manner, then will show that T is a linear transformation. If it is a linear transformation one has to prove that, T is additive by this I mean to say, that if I take α and β two vectors in \mathbb{R}^3 . Then, T of $\alpha + \beta$ is T of α plus T of β for each α, β in V .

So, let us consider α is $x_1 y_1 z_1$. And β is $x_2 y_2 z_2$, so these are two vectors in \mathbb{R}^3 . Now, T of this is equal to T of this vector. Because, the sum of two vectors is x_1

plus x_2 , this is y_1 plus y_2 and z_1 plus z_2 . So, sum of these two vectors is equal to this. So, T of this is equal to this vector. Now, this transformation says that, the first component will become the first component of $T\alpha$. And the third component will become the second component. So, that way T of x_1 plus x_2 y_1 plus y_2 z_1 plus z_2 will become x_1 x_2 and z_1 plus z_2 .

(Refer Slide Time: 06:23)

$$\begin{bmatrix} x_1 + x_2 \\ y_1 + y_2 \\ z_1 + z_2 \end{bmatrix} = \begin{bmatrix} x_1 \\ y_1 \\ z_1 \end{bmatrix} + \begin{bmatrix} x_2 \\ y_2 \\ z_2 \end{bmatrix} = \left(T \begin{bmatrix} x_1 \\ y_1 \\ z_1 \end{bmatrix} + T \begin{bmatrix} x_2 \\ y_2 \\ z_2 \end{bmatrix} \right)$$

∴ T is additive.

ii) T is homogeneous: $T(c\alpha) = cT(\alpha)$

$$T \left(c \begin{bmatrix} x_1 \\ y_1 \\ z_1 \end{bmatrix} \right) = T \begin{bmatrix} cx_1 \\ cy_1 \\ cz_1 \end{bmatrix} = \begin{bmatrix} cx_1 \\ cy_1 \\ cz_1 \end{bmatrix} = c \begin{bmatrix} x_1 \\ y_1 \\ z_1 \end{bmatrix}$$

$$c T \begin{bmatrix} x_1 \\ y_1 \\ z_1 \end{bmatrix} = c \begin{bmatrix} x_1 \\ y_1 \\ z_1 \end{bmatrix}$$

Now, this will simplify to x_1 z_1 plus x_2 z_2 . And by definition of the transformation T x_1 z_1 is T of x_1 y_1 z_1 and x_2 z_2 is T of x_2 y_2 z_2 . And that is how, we have prove that T of α plus β is equal to T of α plus T of β . And that proves the additive property. Now, we prove that T is homogeneous for this purpose, we have to show that T of $c\alpha$ is equal to c times $T\alpha$ c be in a scalar.

Now, to prove this let us consider α is x_1 y_1 z_1 in the scalar c . Then T of c times x_1 y_1 z_1 is equal to T of $c x_1$ $c y_1$ $c z_1$. What I have done is I have taken this scalar c inside this. So, this is equal to c of x_1 and c times z_1 . So, T of this three dimensional vector is this two dimensional vector. And from this, we can take c outside. And what we have is c times x_1 z_1 . And that means, c times T of this is equal to c times this vector. That means, this a vector in \mathbb{R}^3 maps to a vector in \mathbb{R}^2 . So, c times $T x_1 y_1 z_1$ is equal to c times $x_1 z_1$ and that proves the homogenous property. And hence, it is a linear transformation.

(Refer Slide Time: 07:57)

Example 2: show that $T : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ defined below is a linear transformation

$$T \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{pmatrix} rx \\ ry \\ rz \end{pmatrix}$$

Solution:

Consider

$$T \left(c \begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} + \begin{pmatrix} x_2 \\ y_2 \\ z_2 \end{pmatrix} \right) = T \begin{pmatrix} cx_1 + x_2 \\ cy_1 + y_2 \\ cz_1 + z_2 \end{pmatrix}$$

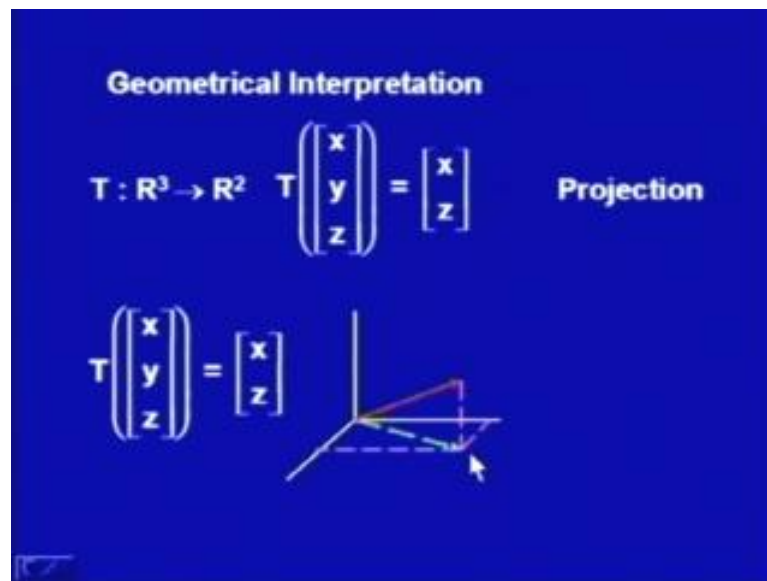

In this, we have again define a linear transformation from \mathbb{R}^3 to \mathbb{R}^3 . And we will again show that it is a linear transformation. So, the transformation is T of x y z is r times r x r y and r z . Now to prove this are again we have to first show the linear property. So it is c times x_1 y_1 z_1 plus x_2 y_2 z_2 . Now, I am combining the two prosperities, the homogenous as well as the additive property. So, I will say T time T of c x_1 y_1 z_1 plus x_2 y_2 z_2 is equal to T times c x_1 plus x_2 , c y_1 plus y_2 , c z_1 plus z_2 , so basically I have combine these two vectors in this form.

(Refer Slide Time: 09:06)

$$\begin{pmatrix} r(cx_1 + x_2) \\ r(cy_1 + y_2) \\ r(cz_1 + z_2) \end{pmatrix} = c \begin{pmatrix} rx_1 \\ ry_1 \\ rz_1 \end{pmatrix} + \begin{pmatrix} rx_2 \\ ry_2 \\ rz_2 \end{pmatrix}$$
$$T \left(c \begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} + \begin{pmatrix} x_2 \\ y_2 \\ z_2 \end{pmatrix} \right) = cT \begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} + T \begin{pmatrix} x_2 \\ y_2 \\ z_2 \end{pmatrix}$$

Now, using the definition for the linear transformation. This expression can be simplified to r times c x_1 plus x_2 , r times c y_1 plus y_2 , r times c z_1 plus z_2 . That is the effect of the transformation is that each component is r times the original value. So, this left hand side is now c times r x_1 r y_1 r z_1 plus r x_2 r y_2 r z_2 , it is a sum of two vectors. And that means, the transformation T applied an c times first vector plus the second vector is equal to c times the transformation applied on the first vector plus transformation applied on the second vector. This proves that T is a linear transformation.

(Refer Slide Time: 09:56)

Now, I will give geometrical interpretation to the examples, which we have taken so far. The first example is the linear transformation T define from \mathbb{R}^3 into \mathbb{R}^2 is T times x y z is equal to x z . You may call it a projection transformation. Let us, consider this vector, this is the vector three dimensional vector x y z it is this is x axis, y axis, z axis. This is the x component, this is the y component and this is the z component.

Now, when T this vector when we consider T of this vector, then what we have is x z . So, what is x z , this is x and this is z . So, this is the vector which is the projection of this vector. So, this transformation means, that this vector is projected this vector has a projection this. So, when we applied linear transformation on this vector, what we get is this projected vector.

(Refer Slide Time: 11:07)

Geometrical Interpretation

$$T: \mathbb{R}^3 \rightarrow \mathbb{R}^3 \quad T \begin{pmatrix} x \\ y \\ z \end{pmatrix} = \begin{bmatrix} rx \\ ry \\ rz \end{bmatrix} = r \begin{bmatrix} x \\ y \\ z \end{bmatrix} \quad \text{Rotation}$$

contraction for $0 < r < 1$
dilation when $r > 1$

So, the second example we consider the vector α in \mathbb{R}^3 as $\begin{pmatrix} x \\ y \\ z \end{pmatrix}$. This is the vector $\begin{pmatrix} x \\ y \\ z \end{pmatrix}$, it has three components x , y and z . Now, when we apply linear transformation on it. Then, it becomes $r \begin{pmatrix} x \\ y \\ z \end{pmatrix}$, so $r \begin{pmatrix} x \\ y \\ z \end{pmatrix}$ this is $r \begin{pmatrix} x \\ y \\ z \end{pmatrix}$, this is $r \begin{pmatrix} x \\ y \\ z \end{pmatrix}$ and this $r \begin{pmatrix} x \\ y \\ z \end{pmatrix}$. So each of these is r times these values. So, $r \begin{pmatrix} x \\ y \\ z \end{pmatrix}$, $r \begin{pmatrix} x \\ y \\ z \end{pmatrix}$, $r \begin{pmatrix} x \\ y \\ z \end{pmatrix}$ are these components and then the vector will be this vector. So, this vector will be transform to this vector.

And what we have seen that, this vector is rotated to this vector, when we apply this linear transformation. And that is why we call this transformation as rotation. Now, in the process if r is less than 1, it is a positive number lying between 0 and 1. Then we say this is contraction and when r is greater than 1 we say it is dilation.

(Refer Slide Time: 12:28)

Example 3: The following transformation is not a linear transformation:

$$T \begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} = \begin{pmatrix} 2x_1 \\ y_1 + 1 \\ 3z_1 \end{pmatrix}$$

Solution: Consider

$$T \left(c \begin{pmatrix} x_1 \\ y_1 \\ z_1 \end{pmatrix} + \begin{pmatrix} x_2 \\ y_2 \\ z_2 \end{pmatrix} \right) = T \begin{pmatrix} cx_1 + x_2 \\ cy_1 + y_2 \\ cz_1 + z_2 \end{pmatrix} = \begin{pmatrix} 2(cx_1 + x_2) \\ cy_1 + y_2 + 1 \\ 3(cz_1 + z_2) \end{pmatrix}$$

Then next example, T of $x_1 \ y_1 \ z_1$ is equal to $2x_1 \ y_1 + 1 \ 3z_1$. And the third component is $3z_1$. So, the transformation from \mathbb{R}^3 to \mathbb{R}^3 this transformation is not a linear transformation. So, what we have to do is that this linear property is not satisfied for this transformation. So, let us consider T applied on c times first vector plus second vector in the domain set domain vector space. So, it is T times $c \ x_1$ plus x_2 if I combine the two. Second component is $c \ y_1$ plus y_2 and $c \ z_1$ plus z_2 .

Now, then T operated on this vector then according to this definition, the first component is two times this. So, it is 2 times $c \ x_1$ plus x_2 . The second component will map to $y_1 + 1$. So $c \ y_1$ plus y_2 becomes $c \ y_1$ plus $y_2 + 1$. And the third component $c \ z_1$ plus z_2 will becomes 3 times this component. So, $c \ z_1$ plus z_2 is 3 times $c \ z_1$ plus z_2 , so T of this vector is this.

(Refer Slide Time: 13:51)

$$\begin{aligned} &= \begin{bmatrix} 2cx_1 + 2x_2 \\ cy_1 + y_2 + 1 \\ 3cz_1 + 3z_2 \end{bmatrix} = c \begin{bmatrix} 2x_1 \\ y_1 + 1 \\ 3z_1 \end{bmatrix} + \begin{bmatrix} 2x_2 \\ y_2 \\ 3z_2 \end{bmatrix} = cT \begin{bmatrix} x_1 \\ y_1 \\ z_1 \end{bmatrix} + \begin{bmatrix} 2x_2 \\ y_2 \\ 3z_2 \end{bmatrix} \\ &\neq cT \begin{bmatrix} x_1 \\ y_1 \\ z_1 \end{bmatrix} + T \begin{bmatrix} x_2 \\ y_2 \\ z_2 \end{bmatrix} \end{aligned}$$

So, let us simplified this, so T 2 times c x 1 plus 2 times as x 2 is c times 2 x 1 plus 2 x 2, but when we come to this, this c y 1 plus y 2 plus 1. It is c y 1 plus y 1 plus 1 plus y 2, c y 1 plus 1 and y 2. And this is c can be taken out is 3 z 1 plus 3 z 2. So, this vector is nothing but c times T of x 1 y 1 z 1 plus this vector. But, this vector is not T of this vector, because plus 1 is missing from here. So, what we can say is a linear property is not satisfy or we can say that this is not equal to c T of x 1 y 1 plus z 1, that is T of x 2 y 2 z 2 to the this transformation is not a linear transformation.

(Refer Slide Time: 14:45)

Simple examples of $T : V \rightarrow V$ are

i) Identity transformation denoted by I such that $I(\alpha) = \alpha$

$$I(a\alpha + \beta) = aI(\alpha) + I(\beta)$$
$$a\alpha + \beta = a\alpha + \beta$$

ii) Zero transformation denoted by θ such that $\theta(\alpha) = \theta$

Apart from these examples, there are some simple examples of linear transformations from V to V . The first is the identity transformation, denoted by I . Such that, every vector in V maps to itself. Since a transformation from V to V . So, every vector α in V will map to itself such a transformation is identity transformation. And one can easily see, that it actually satisfies this property. Like $I(\alpha + \beta) = I\alpha + I\beta$.

And that means, I applied on $\alpha + \beta$ is $\alpha + \beta$. And I applied on α is α and I applied on β is β . So, both sides are equal and one can say that, identity transformation is a linear transformation. The other simple example is the zero transformation, denoted by θ . And we define it as $\theta(\alpha) = 0$. That means, every vector α in this vector space V will map to the additive identity. So this is a 0 transformation as a θ every vector α will now map to 0. So, this also satisfies linear properties that can be very easy to prove and is a linear transformation.

(Refer Slide Time: 16:17)

Example 4: Let $T: \mathbb{R}^2 \rightarrow \mathbb{R}^3$ be defined as $TX = AX$ for X in \mathbb{R}^2 and TX in \mathbb{R}^3 . A is the matrix 3×2 matrix:

$$T \begin{bmatrix} x \\ y \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x \\ y \end{bmatrix}$$

Show that T is a linear transformation.

Solution:

$$T(c\alpha + \beta) = T\left(c \begin{bmatrix} x_1 \\ y_1 \end{bmatrix} + \begin{bmatrix} x_2 \\ y_2 \end{bmatrix}\right) = T \begin{bmatrix} cx_1 + x_2 \\ cy_1 + y_2 \\ cz_1 + z_2 \end{bmatrix}$$

This is another example, here we define the linear transformation T from \mathbb{R}^2 to \mathbb{R}^3 . And it is defined as $TX = AX$ for X in \mathbb{R}^2 and TX in \mathbb{R}^3 , where A is the matrix of 3 by 2 order. So, let us define this transformation T as x and y ((Refer Time: 16:34)) in \mathbb{R}^2 will map to this vector in \mathbb{R}^3 . Now, we show that T is a linear transformation. Now, again the method of proof is the same, we start with $c\alpha + \beta$.

And the vector $c\alpha + \beta$ will be we operate T on this. And what we have is T times $c x_1 y_1$ plus $x_2 y_2$ set is a two dimensional vector. So, α is the $x_1 y_1$ and β is $x_2 y_2$, when this is operated on T when T is operated on this vector. Then we should have T times $c x_1$ plus x_2 , $c y_1$ plus y_2 $c z_1$ plus z_2 .

(Refer Slide Time: 17:18)

$$\begin{aligned}
 &= \begin{bmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} cx_1 + x_2 \\ cy_1 + y_2 \end{bmatrix} = \begin{bmatrix} cx_1 + x_2 \\ cx_1 + x_2 + cy_1 + y_2 \\ cy_1 + y_2 \end{bmatrix} \\
 T(c\alpha + \beta) &= c \begin{bmatrix} x_1 \\ x_1 + y_1 \\ y_1 \end{bmatrix} + \begin{bmatrix} x_2 \\ x_2 + y_2 \\ y_2 \end{bmatrix} \\
 &= c \begin{bmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_1 \\ y_1 \end{bmatrix} + \begin{bmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x_2 \\ y_2 \end{bmatrix} \\
 &= c T(\alpha) + T(\beta).
 \end{aligned}$$

Hence it is a linear Transformation.

And that means, $\begin{bmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{bmatrix}$ this is the definition of this linear transformation. And when we multiply it is $c x_1$ plus x_2 this multiplied by this is $c x_1$ plus x_2 and plus $c y_1$ plus y_2 and then this is equal to $c y_1$ plus y_2 . And then $T(c\alpha + \beta)$ one can see that this is equal to c times x_1 second component $x_1 + y_1$ and third component is y_1 and plus from here, we can write down x_2 this $x_2 + y_2$ the second component and what we have is y_2 .

So, $T(c\alpha + \beta)$ is equal to c times $\begin{bmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{bmatrix} x_1 y_1$ plus $\begin{bmatrix} 1 & 0 \\ 1 & 1 \\ 0 & 1 \end{bmatrix} x_2 y_2$. So, if we use that this is actually equivalent to this and this means that this is c times $T\alpha$ plus $T\beta$ and that proves that it is a linear transformation.

(Refer Slide Time: 18:31)

SOME IMPORTANT RESULTS

Theorem 1: Let $T : V \rightarrow W$ is a linear Transformation then

i) $T(\theta_1) = \theta_2$ where θ_1 is identity vector in V , θ_2 is the identity vector in W

ii) $T(\alpha - \beta) = T(\alpha) - T(\beta)$

Proof:

i) $T(\theta_1) = T(\theta_1 + \theta_1) = T(\theta_1) + T(\theta_1)$
 $\therefore T(\theta_1) = \theta_2$

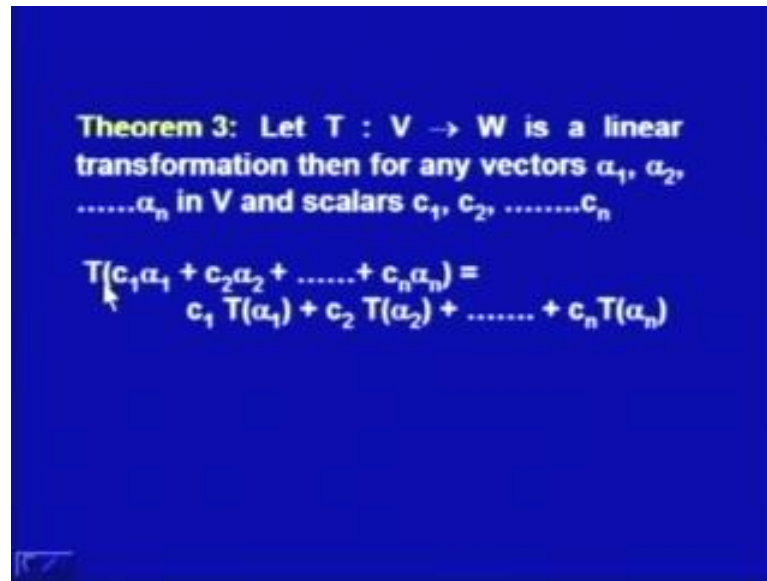

ii) $T(c\beta + \alpha) = cT(\beta) + T(\alpha)$ Take $c = -1$
 $T(\alpha - \beta) = T(\alpha) - T(\beta)$

Now, we will discuss some important results in the form of theorems, theorem 1 says that if T is a linear transformation from the vector space V into W . Then, the first result is that T of θ_1 is equal to θ_2 , where θ_1 is identity vector in V and θ_2 is the identity vector in W . The second result says that T of α minus β is equal to T of α minus T of β . Then, the first result says that the identity vector of V under this transformation will map to identity vector of W .

Now, and this says that this we have additive property, now this is the subtraction, now let us consider the proof for the first property. So, we can write down T of θ_1 , what is θ_1 , θ_1 is identity vector in V . So, when identity vector is added into identity vector what we have is identity. So, θ_1 can be written as θ_1 plus θ_1 , so T of θ_1 plus θ_1 since T is linear becomes T of θ_1 plus T of θ_1 .

And that means, T of θ_1 is nothing but the θ_2 because, T of θ_1 is equal to θ_2 plus T of θ_1 , this is possible only if T of θ_1 is equal to θ_2 . And this shows that the identity of V will map to identity of W to prove the second property we consider T of c of α plus β is equal to c of T of β plus T of α . Because, T is a linear transformation, but what we can do is, we can simply take c is equal to minus 1. And that means T of α minus β is equal to T of α minus T of β , so proof of this second property is also simple.

(Refer Slide Time: 20:35)

Theorem 3: Let $T : V \rightarrow W$ is a linear transformation then for any vectors $\alpha_1, \alpha_2, \dots, \alpha_n$ in V and scalars c_1, c_2, \dots, c_n

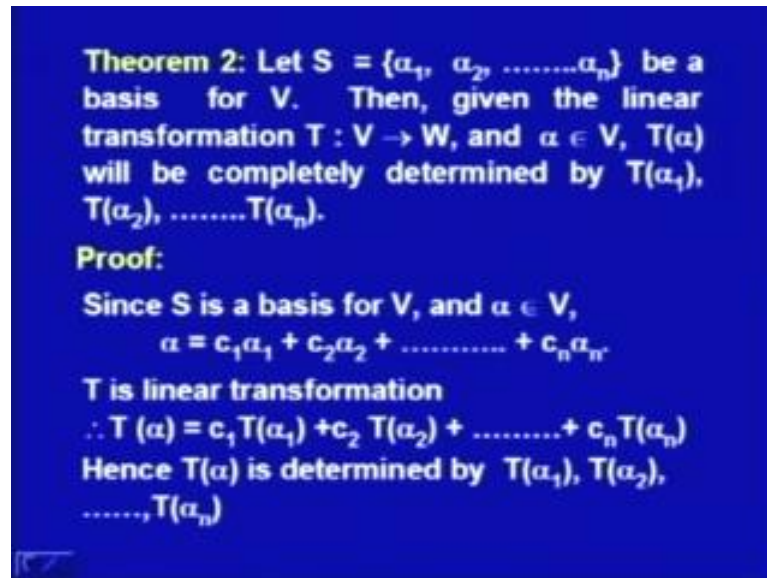

$$T(c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n) = c_1 T(\alpha_1) + c_2 T(\alpha_2) + \dots + c_n T(\alpha_n)$$

Now, some more results T is a linear transformation from V to W , then for any vector $\alpha_1, \alpha_2, \alpha_n$ in V and the scalars c_1, c_2, c_n . Then, T of $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n$ is equal to $c_1 T(\alpha_1) + c_2 T(\alpha_2) + \dots + c_n T(\alpha_n)$, what we are going to do is, we have n vectors here we have n scalars what we have done is, we have taken the linear combination of and the vectors $\alpha_1, \alpha_2, \alpha_n$ and the scalar c_1, c_2, c_n .

Now, T of this vector now since we have V as a vector space. So, if $\alpha_1, \alpha_2, \alpha_n$, they belong to V . So, this linear combination will also belong to V . So, this is also vector in V and T is a linear transformation. Then, this T times this vector is equal to $c_1 T(\alpha_1) + c_2 T(\alpha_2) + \dots + c_n T(\alpha_n)$. If we have only two vectors or we can say n is equal to 2, then T of $c_1\alpha_1 + c_2\alpha_2$ is equal to $c_1 T(\alpha_1) + c_2 T(\alpha_2)$, this super position property, but actually these are n vectors.

So, to prove this what we can do is, we can consider $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n$, we can take this as one vector and we are $c_1\alpha_1$ one vector plus another vector linear property can applied. So, we will have $c_1 T(\alpha_1)$ plus the second vector or the second vector the same thing can be applied with second vector repeatedly. And what will have a final result that T of $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n$ is equal to $c_1 T(\alpha_1) + c_2 T(\alpha_2) + \dots + c_n T(\alpha_n)$. So, basically a generalization of what we had earlier, so for that is result was for two vectors this is for n vectors.

(Refer Slide Time: 22:39)

Theorem 2: Let $S = \{\alpha_1, \alpha_2, \dots, \alpha_n\}$ be a basis for V . Then, given the linear transformation $T : V \rightarrow W$, and $\alpha \in V$, $T(\alpha)$ will be completely determined by $T(\alpha_1), T(\alpha_2), \dots, T(\alpha_n)$.

Proof:

Since S is a basis for V , and $\alpha \in V$,

$$\alpha = c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n$$

T is linear transformation

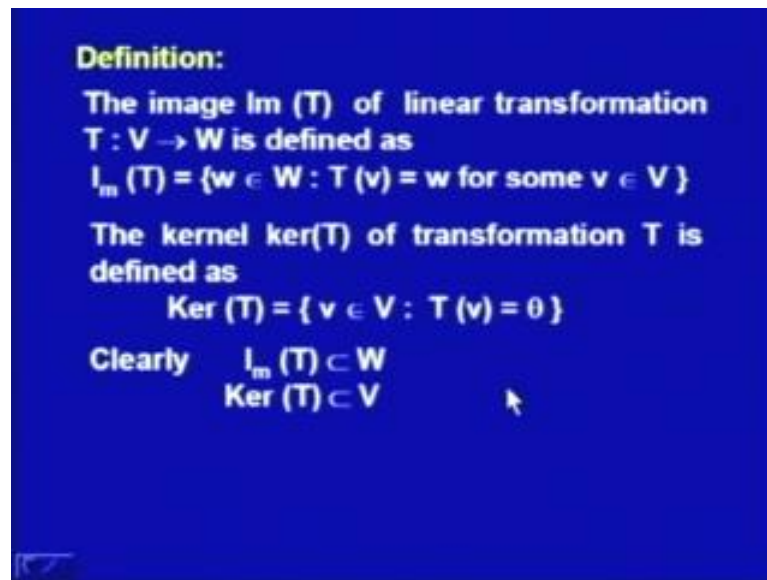

$$\therefore T(\alpha) = c_1T(\alpha_1) + c_2T(\alpha_2) + \dots + c_nT(\alpha_n)$$

Hence $T(\alpha)$ is determined by $T(\alpha_1), T(\alpha_2), \dots, T(\alpha_n)$

Now, since V is the vector space, so it may be having basis. So, let us consider S is a basis for the vector V . Then, given the linear transformation T and α belonging to V , then $T(\alpha)$ will be completely determined by it is ((Refer Time: 23:00)) $T(\alpha_1), T(\alpha_2), \dots, T(\alpha_n)$, the idea is that what will happen to these vectors $\alpha_1, \alpha_2, \dots, \alpha_n$.

So, we have these are basis this V is n dimensional vector space. Then, $T(\alpha)$ being the image of a vector at V , then the inner vector will be determined in terms of $T(\alpha_1), T(\alpha_2), \dots, T(\alpha_n)$. So, let us prove this, since S is a basis for V and α belong to V , then α which a linear combination of these vectors S being the basis can be written α is equal to $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n$, then if T is a linear transformation. So, at $T(\alpha)$ is equal to $c_1T(\alpha_1) + c_2T(\alpha_2) + \dots + c_nT(\alpha_n)$. Now, this is the result which we I have just established in my last theorem. Then, $T(\alpha)$ is determined by $T(\alpha_1), T(\alpha_2), \dots, T(\alpha_n)$, how see this vector α is determined by a the scalar c_1, c_2, \dots, c_n and this α_1 maps to $T(\alpha_1)$, α_2 maps to $T(\alpha_2)$, α_n maps to $T(\alpha_n)$. So, c_1, c_2, \dots, c_n uniquely determine, so $T(\alpha)$ will also be uniquely determined and hence, we can say that $T(\alpha)$ is determined by $T(\alpha_1), T(\alpha_2), \dots, T(\alpha_n)$.

(Refer Slide Time: 24:39)

Definition:
The image $\text{Im}(T)$ of linear transformation $T: V \rightarrow W$ is defined as
$$\text{Im}(T) = \{w \in W : T(v) = w \text{ for some } v \in V\}$$

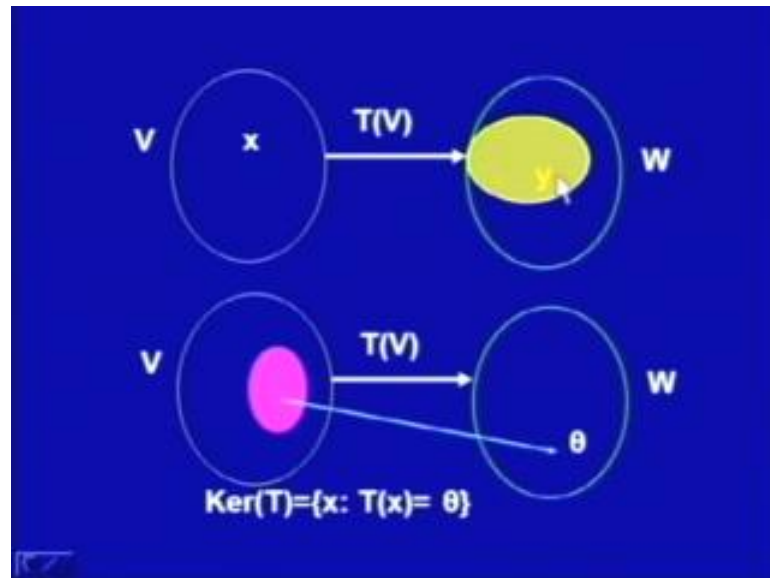

The kernel $\text{ker}(T)$ of transformation T is defined as
$$\text{Ker}(T) = \{v \in V : T(v) = 0\}$$

Clearly $\text{Im}(T) \subset W$
 $\text{Ker}(T) \subset V$

Now, we will introduce more concepts to start with the image T of linear transformation T from V to W is defined as the set consisting of all W s. Such that $T v$ is equal to W for some v belonging to V . Sometimes, this is also called as range of T , the kernel T of transformation T is defined as the set consisting of all vectors v in V . Such that, $T v$ is equal to identity in W , that way we defined two sets image T of range T and kernel T .

So, these two sets are related with that linear transformation T , clearly image T is a subset of W and kernel T is a subset of V . In fact, it is prove that image T is sub space of W , W being the vector space, kernel T is the sub space of V .

(Refer Slide Time: 25:46)

Let us show it pictorially we have two vector spaces V and W x belongs to V and under this transformation T this vector x will go to y . Now, this is the image set which is consisting of all y 's which has some point x in the set V . So, y is an image of x all these y 's include the range or image set which is contained in W .

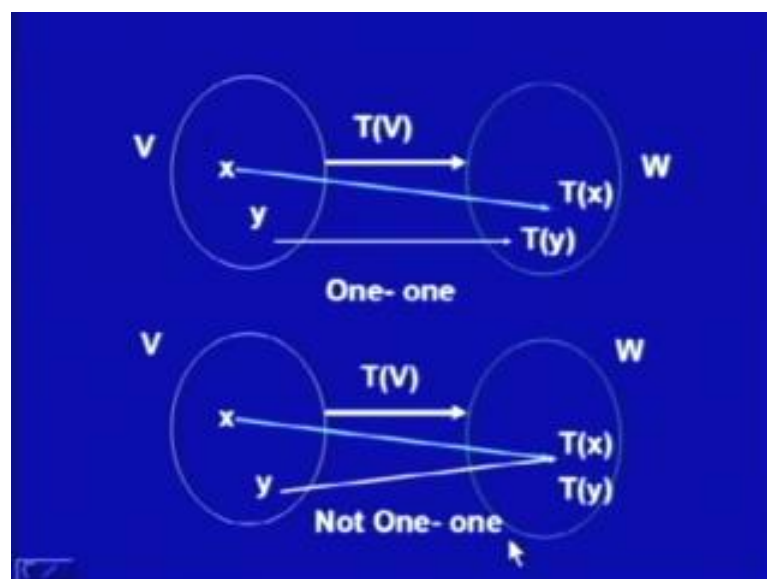

Now, for the kernel T this is the domain, in which the vectors will map to the identity vector θ in W . So, all these vectors in this domain will map to θ . So, kernel T is the set of all x in V such that $T x$ is equal to θ , so this is a subset of V and this is a subset of W .

(Refer Slide Time: 26:56)

Definition:
A linear transformation $T : V \rightarrow W$ is said to be one - one if $\alpha \neq \beta \in V \Rightarrow T(\alpha) \neq T(\beta)$
or T is one - one if $T(\alpha) = T(\beta) \Rightarrow \alpha = \beta$.
A linear transformation $T : V \rightarrow W$ is said to be onto when $\text{range}(T) = W$
A linear transformation $T : V \rightarrow W$ is an isomorphism if it is one - one onto . The vector spaces V and W are said to be isomorphic if there is an isomorphism of V into W .

Now, we say that a linear transformation T is said to be one-one if $\alpha \neq \beta$ belonging to V , implies that $T(\alpha)$ and $T(\beta)$ they are not the same. That means, if we have two different elements in V , then their images cannot be the same they have to be different. That is, if T is one-one, then if $T(\alpha) = T(\beta)$ then α and β have to be the same, a linear transformation T is said to be onto when range of T is equal to W . And another definition if T the linear transformation from V into W is an isomorphism if it is one-one onto. The vector space V and W are said to be isomorphic, if there is an isomorphism of V into W .

(Refer Slide Time: 27:56)

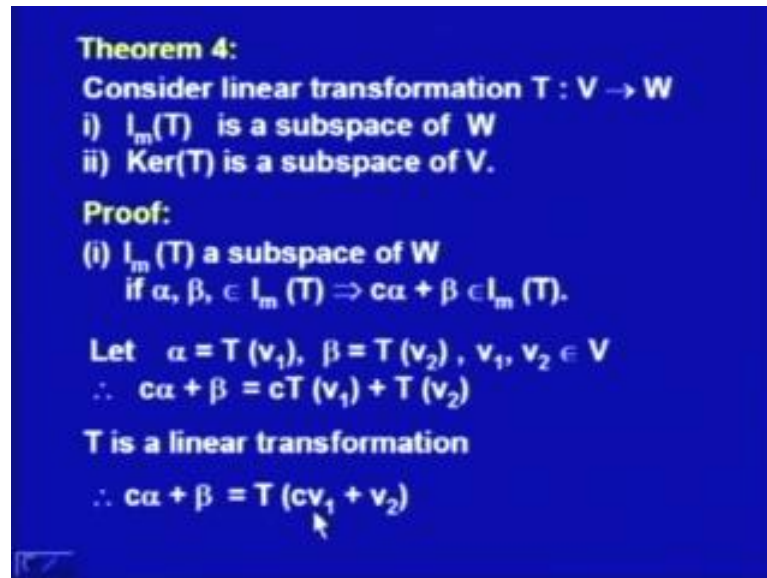

Again, we show it here we have two different elements, two different vectors in V the map to different vectors in W . So, x maps to $T x$ and y maps to $T y$, this is true for any combination of x and y in V , then we say that the linear transformation is one-one. In another example, here we have 2 x and y in V , but both map to same element in W , that is x and y are different in V , but they are same in W and that means this transformation T is not one-one.

(Refer Slide Time: 28:39)

Now, in this case we have of the vector space V and a vector space W , T is a linear transformation x maps to this element $T x$ in W y maps to this element $T y$ in an W . And this is the set, in which we will have images of in which the elements in V will map to this set. That means, if this set and set W they have become the same, then it becomes an onto transformation. That means, there is no element in this W , which is not an image of this every element here is in image is image of some point in V that is onto transformation.

(Refer Slide Time: 29:27)

Theorem 4:
Consider linear transformation $T : V \rightarrow W$
i) $I_m(T)$ is a subspace of W
ii) $\text{Ker}(T)$ is a subspace of V .

Proof:
(i) $I_m(T)$ a subspace of W
if $\alpha, \beta, \in I_m(T) \Rightarrow c\alpha + \beta \in I_m(T)$.

Let $\alpha = T(v_1), \beta = T(v_2), v_1, v_2 \in V$
 $\therefore c\alpha + \beta = cT(v_1) + T(v_2)$

T is a linear transformation
 $\therefore c\alpha + \beta = T(cv_1 + v_2)$

Now, we can prove these theorems that consider linear transformation T , then image T is a sub space of W and kernel T is a subspace of V . So, image T is a subspace of W and kernel T is a sub space of V . Now, first we prove the first result that image T is a subspace of W . So, to prove this we consider α, β belonging to image T . Then, if $c\alpha + \beta$ also belongs in image T , then image T is a subspace this is a very definition of subspace.

So, we consider α and β belonging to image T , so if they belong image T . That means, there must be some v_1 in the set V , so that α is equal to $T v_1$ and some v_2 in V , so that β is equal to $T v_2$. So, let us consider α and β in this way. So, $c\alpha + \beta$ is equal to $c T v_1 + T v_2$. And since, T is a linear transformation, so $c\alpha + \beta$ is equal to $T(cv_1 + v_2)$.

(Refer Slide Time: 30:49)

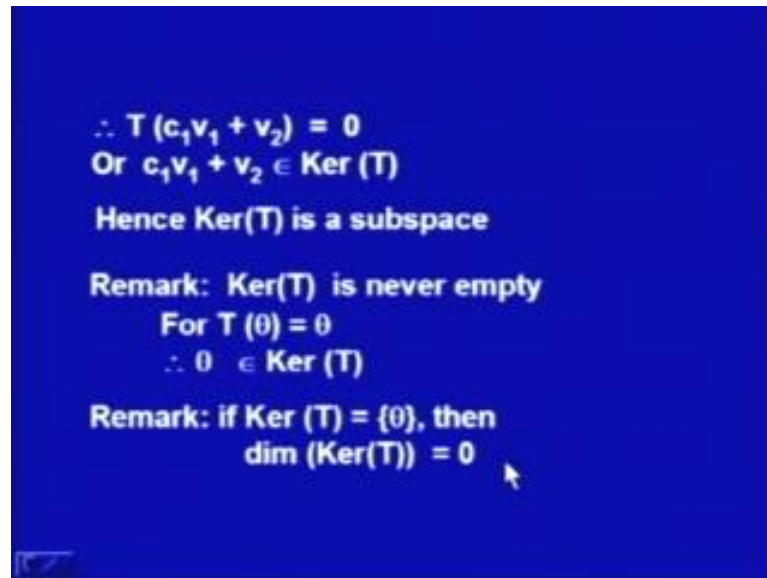

Since V is a subspace
 $\therefore v_3 = cv_1 + v_2 \in V$
 $\therefore c\alpha + \beta = T(v_3)$
Or $c\alpha + \beta \in \text{Im}(T)$ $\text{Im}(T)$ is a subspace.

ii) $\text{Ker}(T)$ is a subspace of V
if $v_1, v_2 \in \text{Ker}(T) \Rightarrow c_1v_1 + v_2 \Rightarrow \text{Ker}(T)$
Let $v_1, v_2 \in \text{Ker}(T)$
 $\Rightarrow T(v_1) = 0$ and $T(v_2) = 0$
 T is Linear Transformation
 $\therefore T(c_1v_1 + v_2) = c_1T(v_1) + T(v_2)$

Now, V is a subspace therefore, $c v_1 + v_2$ they also belongs to v , let us call this vector as v_3 . Then, $c\alpha + \beta$ is equal to T of v_3 . That means, $c\alpha + \beta$ is an image of v_3 and; that means, $c\alpha + \beta$ also belong to image T and this proves that image T is a subspace. On the second part of the theorem is that kernel T is a subspace of v .

So, we consider two vectors in kernel T v_1 and v_2 and will prove that $c v_1 + v_2$ is also in kernel T that is the definition of subspace. So, we start with v_1, v_2 belonging to kernel T . So, if they belong to kernel T this implies that $T v_1$ is equal to identity θ and $T v_2$ is equal to θ . Now, since T is a linear transformation, then T of $c v_1 + v_2$ is equal to $c T v_1 + T v_2$.

(Refer Slide Time: 32:07)

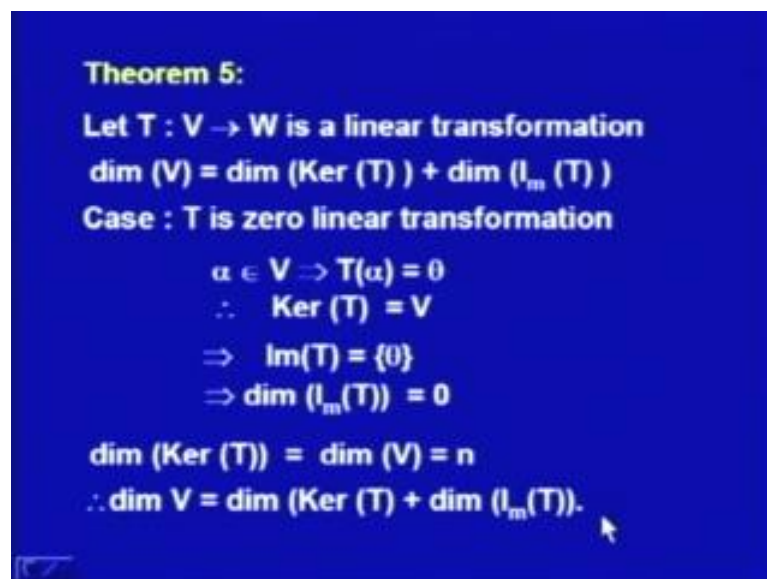

$\therefore T(c_1v_1 + v_2) = 0$
Or $c_1v_1 + v_2 \in \text{Ker}(T)$
Hence $\text{Ker}(T)$ is a subspace

Remark: $\text{Ker}(T)$ is never empty
For $T(0) = 0$
 $\therefore 0 \in \text{Ker}(T)$

Remark: if $\text{Ker}(T) = \{0\}$, then
 $\dim(\text{Ker}(T)) = 0$

And that means, T of $c_1v_1 + v_2$ is also 0 and this proves that $c_1v_1 + v_2$ also belongs to kernel T and that is kernel T is a subspace. Now, there is remark that kernel T is never empty because, T of 0 is equal to 0 . So, there is always a vector 0 a kernel T , which will map 0 itself. So, kernel T will never empty 0 will always belong kernel T there may be more members in kernel T . But, this will 0 will always be in kernel T and it is never empty. Then, secondary mark is, if kernel T is 0 only then dimension of kernel T is equal to 0 this is another remark.

(Refer Slide Time: 33:03)

Theorem 5:
Let $T : V \rightarrow W$ is a linear transformation
 $\dim(V) = \dim(\text{Ker}(T)) + \dim(\text{Im}(T))$
Case : T is zero linear transformation

$\alpha \in V \rightarrow T(\alpha) = 0$
 $\therefore \text{Ker}(T) = V$
 $\Rightarrow \text{Im}(T) = \{0\}$
 $\Rightarrow \dim(\text{Im}(T)) = 0$

$\dim(\text{Ker}(T)) = \dim(V) = n$
 $\therefore \dim V = \dim(\text{Ker}(T)) + \dim(\text{Im}(T))$

Then, we have an important result regarding dimension of kernel T and dimension of image T of range T . And it says that, if T is that linear transformation from V into W , then dimension of V is equal to dimension of kernel T plus dimension of image T . Now, to prove this result we prove it in two different cases, the first case is the T is the 0 transformation.

So, if T is a 0 transformation then α belongs to v implies that $T\alpha$ is equal to θ and kernel T in that case will be V and image T will be θ itself and dimension of image T in that case will be 0 or dimension of kernel T is equal to dimension of V is equal to n . So, dimension of V is equal to dimension of kernel T plus dimension of image T . So, that we have proved the first part, when T is an 0 linear transformation, the second case is the dimension of kernel T is k it is not 0 .

(Refer Slide Time: 34:27)

Case: $\dim(\ker(T)) = k \neq 0$,
 To prove $\dim(\text{Im}(T)) = n - k$
 Let the basis for $\text{Ker}(T) = \{\alpha_1, \alpha_2, \dots, \alpha_k\}$
 $\text{Ker}(T) \subseteq V$
 To prove $\text{Im}(T) = \{\alpha_{k+1}, \dots, \alpha_n\}$
 Basis for $V = \{\alpha_1, \alpha_2, \dots, \alpha_k, \alpha_{k+1}, \dots, \alpha_n\}$
 Let $\beta \in \text{Im}(T)$, $\beta = T(\alpha)$ for some α in V
 $\therefore \alpha = c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n$
 $\therefore \beta = T(c_1\alpha_1 + c_2\alpha_2 + \dots + c_k\alpha_k + c_{k+1}\alpha_{k+1} + \dots + c_n\alpha_n)$

Now, to prove this we have to prove the dimension of image T is n minus k , so for this let us say that basis for kernel T is $\alpha_1, \alpha_2, \dots, \alpha_k$ and kernel T being a subspace of V , we have to prove that image T is equal to $\alpha_{k+1}, \dots, \alpha_n$. So, this is what we are going to prove. So, image T is actually generated by this set, so basis for V is let us consider it to be $\alpha_1, \alpha_2, \dots, \alpha_k, \alpha_{k+1}, \dots, \alpha_n$.

So, we have n dimensional vector space V and the basis $\alpha_1, \alpha_2, \dots, \alpha_k$, this is the basis for kernel T , kernel T be in the subspace of V and we have some additional vectors. So, basis for V is this, let us consider β belonging to image T , then there must

be some alpha in V. So, that beta is equal T of alpha, so we write down this alpha as a linear combination of the vectors of basis of V. That is, alpha is equal to $c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k + c_{k+1} \alpha_{k+1} + \dots + c_n \alpha_n$, then beta is equal to T of this vector.

So, I write down this vector as $c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k + c_{k+1} \alpha_{k+1} + \dots + c_n \alpha_n$. So that means, I have divided this into two parts, this is the vector $c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k$, the linear combination of vectors alpha 1 to alpha k; that means this will belong to kernel T and this is map to 0, so I will use the property of linear transformation.

(Refer Slide Time: 36:32)

T is linear transformation
 $\beta = \{c_1 T(\alpha_1) + c_2 T(\alpha_2) + \dots + c_k T(\alpha_k)\} + c_{k+1} T(\alpha_{k+1}) + \dots + c_n T(\alpha_n)$
 $\beta = T(c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k) + c_{k+1} T(\alpha_{k+1}) + \dots + c_n T(\alpha_n)$
Since ker (T) is a subspace
 $\therefore c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k \in \text{Ker (T)}$
 $\therefore T(c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k) = \theta$
 $\therefore \beta = c_{k+1} T(\alpha_{k+1}) + \dots + c_n T(\alpha_n)$
Every vector in $I_m(T)$ is spanned by
 $B_1 = \{T(\alpha_{k+1}), T(\alpha_{k+2}), \dots, T(\alpha_n)\}$

And I write down beta as $c_1 T \alpha_1 + c_2 T \alpha_2 + \dots + c_k T \alpha_k$ on one side and $c_{k+1} T \alpha_{k+1} + \dots + c_n T \alpha_n$ at the second term. So, I have two term I have represented beta as sum of two terms, this term and this term. And that means, beta is equal to T of $c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k$ plus the second term and this is a kernel T is a subspace. And therefore, $c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k$ belongs to kernel T and that is why T of this is equal to theta.

So, this we use beta is equal to simply this terms. So, beta is equal to $c_{k+1} T \alpha_{k+1} + \dots + c_n T \alpha_n$. Now, every vector in image T is spanned by this set. But, we have to say that if these vectors are linearly independent, then we have prove the result. So, we have just said that any vector beta is a linear combination of $T \alpha_{k+1}$ up to $T \alpha_n$.

(Refer Slide Time: 37:56)

If $T(\alpha_{k+1}), T(\alpha_{k+2}), \dots, T(\alpha_n)$ are linearly independent then B_1 is a basis for $I_m(T)$

$$\therefore d_1 T(\alpha_{k+1}) + d_2 T(\alpha_{k+2}) + \dots + d_{n-k} T(\alpha_n) = 0$$

$$T(d_1 \alpha_{k+1} + d_2 \alpha_{k+2} + \dots + d_{n-k} \alpha_n) = 0$$

$$T(c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k + d_1 \alpha_{k+1} + d_2 \alpha_{k+2} + \dots + d_{n-k} \alpha_n) = 0$$

Since B is a basis

$$c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k + d_1 \alpha_{k+1} + \dots + d_{n-k} \alpha_n = 0$$

$$\Rightarrow c_1 = c_2 = \dots = c_k = d_1 = d_2 = \dots = d_{n-k} = 0$$

$$\Rightarrow \alpha_{k+1}, \alpha_{k+2}, \dots, \alpha_n \text{ are linearly independent}$$

So, it is spanned by this set what we have to see that, they are linearly independent and in that case B_1 is a basis for image T . So, to prove this, let us consider $d_1 T(\alpha_{k+1}) + d_2 T(\alpha_{k+2}) + \dots + d_{n-k} T(\alpha_n) = 0$. So, this linear combination of $n - k$ vectors is 0, now this is 0 then T of $d_1 \alpha_{k+1} + d_2 \alpha_{k+2} + \dots + d_{n-k} \alpha_n$ is a linear property satisfied.

So, T of $d_1 \alpha_{k+1} + d_2 \alpha_{k+2} + \dots + d_{n-k} \alpha_n$ is equal to 0 this is equal to T times I have added $c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k$ I have added this in this because, ((Refer Time: 38:44)) this is mapping to 0, so T of this is 0, so I have added this into this term.

So, since B is a basis, so $c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_k \alpha_k + d_1 \alpha_{k+1} + \dots + d_{n-k} \alpha_n = 0$ means all the scalar terms $c_1, c_2, \dots, c_k, d_1, d_2, \dots$ etcetera are 0, so c_1, c_2 etcetera they are all identically 0. And; that means, $\alpha_{k+1}, \alpha_{k+2}, \dots, \alpha_n$ are linearly independent because, these are 0, so these vectors are linearly independent.

(Refer Slide Time: 39:30)

$\therefore \dim(\text{Im}(T)) = n - k$
 $\dim(\text{Im}(T)) + \dim(\text{Ker}(T)) = \dim(V)$

Remark:
For the linear Transformation T , Rank of T is defined to be the dimension of $\text{Im}(T)$
 $\text{Rank}(T) = \dim(\text{Im}(T))$

Nullity of T is defined to be the dimension of $\text{Ker}(T)$
 $\text{Nullity}(T) = \dim(\text{Ker}(T))$

$\text{Rank}(T) + \text{Nullity}(T) = \dim(V)$

And that means, the dimension of image T is n minus k because, we are having n minus k vectors. So, what we have is dimension of image T plus dimension of kernel T is dimension of v . So, we have proved an important result for the linear transformation T rank of T is defined to be the dimension of image T . This is the definition that rank of T is defined to be the dimension of image T or rank of T is dimension image T , similarly nullity of T is define to be the dimension of kernel T . So, nullity T is dimension of kernel T and in this slide we can say that rank of T plus nullity of T is equal to dimension of V . So, this is an important result and will be using this at number of spaces.

(Refer Slide Time: 40:24)

Theorem 6: A linear transformation $T : V \rightarrow W$ is one to one if and only if $\text{Ker}(T) = \{0\}$.

Proof: (i) Let T is one to one, $\text{Ker}(T) = \{0\}$
Let $\alpha \in V$ such that $T(\alpha) = 0$
Also $T(0) = 0$
 T is one to one $\therefore \alpha = 0$
 $\Rightarrow \text{Ker}(T) = \{0\}$

(ii) Let $\text{Ker}(T) = \{0\}$
then T will be one to one

Now, another result a linear transformation is one to one if and only if kernel T is equal to identity, we have only one element in kernel T that is identity, such a transformation is one to one. Now, to prove this we have to prove two parts one is the T is one to one. Then, kernel T is equal to theta and the other part is if kernel T is equal to theta then T is one to one.

So, let alpha belongs to V such that T alpha is theta also T theta is theta. Because, theta will map to theta itself, this we have proved earlier. So, we have one more alpha which will take which this transformation T will take to theta, now this is one-one mapping. So, alpha has to be theta no two different elements will go to same element theta in W. So, kernel T has to be theta. So, by contradiction we have prove that kernel T is equal to theta. So, this part is proved, the second is if kernel T is equal to theta, then T will be one to one.

(Refer Slide Time: 41:50)

Let α_1 and $\alpha_2 \in V$ such that $T(\alpha_1) = T(\alpha_2)$

$$T(\alpha_1) - T(\alpha_2) = 0$$

$$T(\alpha_1 - \alpha_2) = 0$$

Since $\text{Ker}(T) = \{0\}$

$$\alpha_1 - \alpha_2 = 0$$

$$\alpha_1 = \alpha_2$$

T is one to one.

Now, to prove this result we consider alpha 1 and alpha 2 belonging to V such that T alpha 1 is equal to T of alpha 2. Then, T of alpha 1 minus T alpha 2 is equal to theta. And since, this is a linear transformation T of alpha 1 minus alpha 2 is equal to theta. But, alpha 1 minus alpha 2 will also belong to V, because a V is a subspace. So, there linear combination will also belong to V. So, T of alpha 1 minus alpha 2 is equal to theta, but we have said that only theta can map to this.

So, kernel T is equal to theta, so; that means, alpha 1 minus alpha 2 is equal to theta and that proves alpha 1 is equal to alpha 2. So, this means T is one-one, so even if we have started with two different values it comes out to be that these two vectors are the same and this proves that T is one to one.

(Refer Slide Time: 42:51)

Example: Obtain $\text{Ker}(T)$, its basis and dimension for the linear transformation $T : \mathbb{R}^3 \rightarrow \mathbb{R}^2$ defined as

$$T \begin{pmatrix} a \\ b \\ c \end{pmatrix} = \begin{pmatrix} a + 2b + c \\ -a + 3b + c \end{pmatrix}$$

Solution:
By definition, if $T \begin{pmatrix} a \\ b \\ c \end{pmatrix} = \mathbf{0}$ then $\begin{bmatrix} a \\ b \\ c \end{bmatrix} \in \text{ker}(T)$

So, we have prove the result, now I will take some examples. The first example says that a transformation being given to us from \mathbb{R}^3 to \mathbb{R}^2 $T \begin{pmatrix} a \\ b \\ c \end{pmatrix}$ is equal to a vector in \mathbb{R}^2 $a + 2b + c$ in the first component and $-a + 3b + c$ is the second component. This linear transformation is being given to us, we have to find kernel T and its basis and dimension. So, we will start with the definition of kernel T, if $T \begin{pmatrix} a \\ b \\ c \end{pmatrix}$ is equal to theta then $\begin{pmatrix} a \\ b \\ c \end{pmatrix}$ will belong to kernel T, this kernel T will be a member of \mathbb{R}^3 . So, that is why I have consider three dimension vector $\begin{pmatrix} a \\ b \\ c \end{pmatrix}$. So, T of $\begin{pmatrix} a \\ b \\ c \end{pmatrix}$ will be 0, then $\begin{pmatrix} a \\ b \\ c \end{pmatrix}$ will belong to kernel T.

(Refer Slide Time: 43:46)

$$\begin{aligned} \text{i.e. } & \begin{aligned} a + 2b + c &= 0 \\ -a + 3b + c &= 0 \end{aligned} & \begin{aligned} 5b + 2c &= 0 \\ c &= -5k, \quad b = 2k \end{aligned} \\ \therefore \ker(T) &= \left\{ \begin{bmatrix} k \\ 2k \\ -5k \end{bmatrix}, k \in \mathbb{R} \right\} \\ \text{Basis of } \ker(T) &= \left\{ \begin{bmatrix} 1 \\ 2 \\ -5 \end{bmatrix} \right\} \quad \therefore \dim(\ker(T)) = 1. \\ \text{Rank}(T) + \text{Nullity}(T) &= \dim(V) \\ \text{Dim}(\text{Im}(T)) = \text{Nullity}(T) &= 3 - 1 = 2 \end{aligned}$$

Now, to prove this we have to say that $a + 2b + c = 0$ minus $-a + 3b + c = 0$, this is to be there this is because a kernel T will be θ only. So, a the first component has to be 0 and the second component has to be 0. So, if you simplify then c is equal to minus $5k$ and b is equal to $2k$, we can add the two and we will get this result.

That means, kernel T is equal to the a is k b is equal to $2k$ and c is equal to minus $5k$ k belonging to \mathbb{R} . That means, any vector of this form will satisfy these equations. So, this vector will belong to kernel T . So, basis of kernel T will be $1 \ 2 \ -5$ any vector of this form can be generated from this. So, this is the basis for kernel T . So, kernel T will be having vectors of this form, which will be generated by this vector.

So, this forms a basis of kernel T and since kernel T involves a vector of this form. So, we say that this is the basis having only one vector, so the dimension of kernel T is 1. Now, we make use of rank T a nullity theorem, it says that rank T plus nullity T is equal to dimension V , dimension V is given to be 3 rank a nullity if given to be 1. So, rank T is equal to dimension image T is equal $3 - 1$ is equal to 2, so dimension of image T is 2.

(Refer Slide Time: 45:47)

Example:
Consider the standard basis for \mathbb{R}^3 as $\{e_1, e_2, e_3\}$ and linear transformation $T : \mathbb{R}^3 \rightarrow \mathbb{R}^3$ such that

$$T(e_1) = e_1 + e_2,$$
$$T(e_2) = e_3 + 2e_2,$$
$$T(e_3) = e_1 - e_2 - e_3.$$

Then show that the vectors $T(e_1)$, $T(e_2)$ and $T(e_3)$ are not linearly independent.

Solution: Let $v_1 = T(e_1) = e_1 + e_2$,
 $v_2 = T(e_2) = e_3 + 2e_2$,
 $v_3 = T(e_3) = e_1 - e_2 - e_3$
are vectors in \mathbb{R}^3

In the second example, we consider standard basis for \mathbb{R}^3 being e_1, e_2, e_3 and we consider linear transformation from \mathbb{R}^3 to \mathbb{R}^3 , define in this manner e_1 will map to e_1 plus e_2 T of e_2 will map to e_3 plus $2e_2$ and T of e_3 will map to e_1 minus e_2 minus e_3 . Now, this is the map linear transformation is from \mathbb{R}^3 to \mathbb{R}^3 , in my earlier result I have prove that the if you know how these elements are being mapped, you define the mapping and the mapping can easily be determined.

So, we define the mapping in terms of e mapping of e_1, e_2 and e_3 , so this defines for mapping. Now, you have to show that the vectors $T e_1$ $T e_2$ and $T e_3$ are not linearly independent. So, let us consider v_1 as T of e_1 which is e_1 plus e_2 and v_2 is $T e_2$ which is e_3 plus $2e_2$ we will define here v_3 is $T e_3$ as e_1 minus e_2 minus e_3 , these are three vectors in \mathbb{R}^3 .

(Refer Slide Time: 47:10)

$$\begin{aligned}c_1 T(e_1) + c_2 T(e_2) + c_3 T(e_3) &= 0 \quad (1) \\c_1(e_1 + e_2) + c_2(e_3 + 2e_2) &+ c_3(e_1 - e_2 - e_3) = 0 \\(c_1 + c_3)e_1 + (c_1 + 2c_2 - c_3)e_2 &+ (c_2 - c_3)e_3 = 0\end{aligned}$$

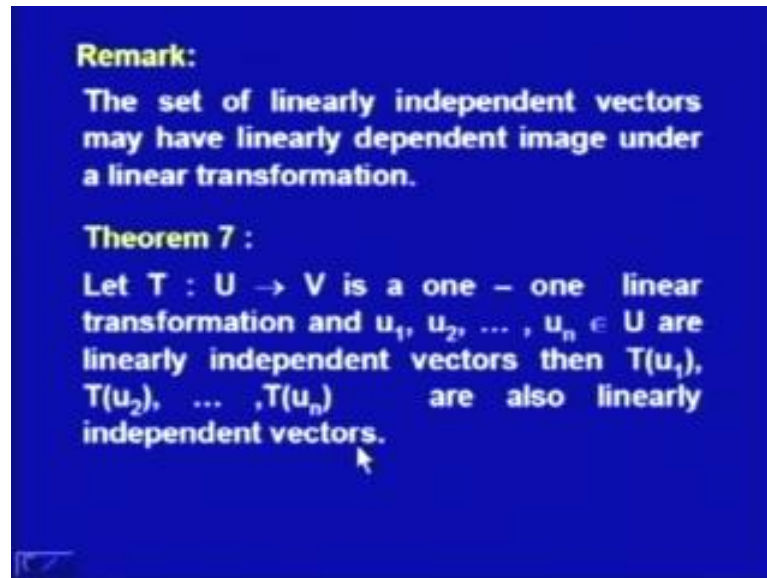

Since e_1, e_2, e_3 are linearly independent
 $c_1 + c_3 = 0, c_1 + 2c_2 - c_3 = 0, c_2 - c_3 = 0$
 $c_1 + c_3 = 0, c_1 + c_2 = 0$
 $c_1 = -k, c_2 = k, c_3 = k$ is possible for (1)
 $T(e_1), T(e_2), T(e_3)$ are linearly dependent.

Let us, consider the linear combination of these three vectors that is $c_1 T_1$ plus $c_2 T_2$ plus $c_3 T_3$ as 0. If these three vectors are linearly independence c_1, c_2, c_3 will come out to be 0. Now, we use the definition of $T e_1, T e_2, T e_3$ been given to us. So, we write down $c_1 e_1$ plus e_2 as $T e_1$ plus $c_2 T e_2$ as e_3 plus $2 e_3$ plus c_3 times $T e_3$ as e_1 minus e_2 minus $e_3 = 0$, we will combine the different terms we will have c_1 plus c_3 multiplied by e_1 plus c_1 plus $2 c_2$ minus c_3 multiplied by e_2 plus c_2 minus c_3 multiplied by e_3 and this is equal to 0.

Since, e_1, e_2, e_3 are linearly independent, therefore c_1 plus c_3 is equal to 0 c_1 plus $2 c_2$ minus c_3 equal to 0, this is the coefficient of e_2 and coefficient of e_3 if c_2 minus c_3 equal to 0. And we have three equations to solve c_1, c_2 and c_3 from the first equation c_1 is equal to minus c_3 and from second c_2 is equal to c_3 . So, if you substitute c_1 plus c_3 is equal to 0 here, then will have c_1 plus c_2 equal to 0.

And that means, c_1 is equal to minus k c_2 is equal to k and c_3 is equal to k is the possible solution for this and k need not be 0. So, we have obtain a solution for this equation, which is nonzero solution and that means, $T e_1, T e_2, T e_3$ are linearly dependent, they cannot be linearly independent, because we have got this nonzero solution.

Remark:
The set of linearly independent vectors may have linearly dependent image under a linear transformation.

Theorem 7 :
Let $T : U \rightarrow V$ is a one – one linear transformation and $u_1, u_2, \dots, u_n \in U$ are linearly independent vectors then $T(u_1), T(u_2), \dots, T(u_n)$ are also linearly independent vectors.

Now, we can put a remark here. The set of linearly independent vectors may have linearly dependent images under a linear transformation. So, this is what has happen in the earlier example, we have started with the linearly independent set of vectors e_1, e_2, e_3 , we have a linear transformation T . But, what we have T of e_1, T of e_2, T of e_3 they are not linearly independent, but they are linearly dependent.

And that is the set of linearly independent vectors may have linearly dependent image, under a linear transformation. Now, this is a theorem we says that, if we have a linear transformation U into V , if it is one-one linear transformation. Then, the set of vectors u_1, u_2, \dots, u_n belonging to U are linearly independent vectors. Then, it is images $T u_1, T u_2, \dots, T u_n$ are also linearly independent vectors. So, the basically this theorem provides a condition under which linearly independent vectors will map to linearly independent vectors. And the result is the that transformation has to be one-one.

(Refer Slide Time: 50:39)

Proof : Consider
 $c_1 T(u_1) + c_2 T(u_2) + \dots + c_n T(u_n) = 0$

Since T is a linear transformation,
 $T(c_1 u_1 + c_2 u_2 + \dots + c_n u_n) = 0$
 $u = c_1 u_1 + c_2 u_2 + \dots + c_n u_n \in U$

T is one - one or Ker (T) = {0}
 $T(u) = 0 \rightarrow u = 0$
 $c_1 u_1 + c_2 u_2 + \dots + c_n u_n = 0$
 $c_1 = c_2 = \dots = c_n = 0$
 $\therefore T(u_1), T(u_2), \dots, T(u_n)$ are linearly independent

So, here is the proof, we can start with a linear combination of that is $T u_1, T u_2, T u_n$. And since, T is a linear transformation. So, will have T of $c_1 u_1$ plus $c_2 u_2$ plus $c_n u_n$ equal to 0. And u will belong to U, because u is a vector space, the linear combination will also belong to U and T is one-one or kernel T is equal to 0.

So, we are been given that T is one-one transformation and we have earlier prove that kernel T is equal to 0 if T is one-one. That means, T of u is equal to 0, so this vector u has to be 0 because, kernel T is equal to 0. And that means, $c_1 u_1$ plus $c_2 u_2$ plus $c_n u_n$ is equal to 0, but we have u_1, u_2, u_n has to be 0; that means, c_1, c_2, c_n has to be 0. So that means, we have a linear combination which is 0 and these ((Refer Time: 51:39)) comes out to be 0 and that means $T u_1, T u_2, T u_n$ are linearly independent.

(Refer Slide Time: 51:49)

Remark: In the example

$$T(e_1) = e_1 + e_2,$$
$$T(e_2) = e_3 + 2e_2$$
$$T(e_3) = e_1 - e_2 - e_3$$
$$T(e_1 - e_2 - e_3) = T(e_1) - T(e_2) - T(e_3)$$
$$= e_1 + e_2 - (e_3 + 2e_2) - (e_1 - e_2 - e_3)$$
$$= 0$$

The vector $e_1 - e_2 - e_3 \in N(T)$

$\dim N(T) = 1$
according to rank - nullity theorem.

$\text{Rank}(T) = \text{Dim}(\text{Im}(T)) = 2$

So, in the of this condition will have a linear independent vectors will go to linearly independent set of vectors. Now, what happen in the earlier example, which was $T e_1$ is equal to e_1 plus e_2 , $T e_2$ was e_3 plus $2 e_2$, $T e_3$ is e_1 minus e_2 minus e_3 . In this example, the vector e_1 minus e_2 minus e_3 is actually linear combination of as $T e_1$ minus $T e_2$ minus $T e_3$ and this is actually 0. And that means, the vector e_1 minus e_2 minus e_3 belongs to N of T and dimension of $N T$ is equal to 1 in that case. So, according to rank nullity theorem, the rank of T is dimension of image T which is 2.

(Refer Slide Time: 52:37)

Let $T : \mathbb{R}^4 \rightarrow \mathbb{R}^6$ be a linear transformation,

If $\dim(\ker T) = 2$, then $\dim(\text{range}(T)) = 2$

If $\dim(\text{range}(T)) = 3$, then $\dim(\ker(T)) = 1$

And in this case they are actually not mapping to the three vectors cannot be linearly independent. Now, I have one more simple result, that if I have a linear transformation from \mathbb{R}^4 to \mathbb{R}^6 . The linear transformation and if dimension of kernel T is given to be 2. Then dimension of range of T or image of T can be computed as 4 minus 2, it is 2, you have to make it clear, that the dimension of V is to be considered in rank nullity theorem not the dimension of W , so there is result here is 2.

Similarly, if dimension of range T is 3 then dimension of kernel T is 1, so 3 plus 1 is equal to 4. So, this rank and nullity theorem can be use to obtained the dimension of kernel T if other two things are given can be obtained for dimension of range T , if dimension of V is given and dimension of kernel T being given to us. Viewers, with this we have come to the end of this lecture to summarize, what we have done today.

I have started with the definition of linear transformation I given some example, I have illustrated with the help of examples, what do you mean by linear transformation? What do you mean by additive property? What do you mean by homogeneous property. And then we have discuss several results related with linear transformations I have introduce the concept of kernel and nullity. And we have finally, established theorem relating range, dimension of range and dimension of kernel with the dimension of the vector space V , we have we will continue with this will discuss more concept related to this in my next lecture.

Thank you.
