Lecture - 28
Applications of Multiple Integrals

Hello friends. So, this lecture is the last lecture from the integral calculus. And in this lecture, I will introduce few applications of multiple integral. So, what I will do? First, I will introduce the applications of double integral, and then I will extend them in case of triple integral.

So, let us start with double integral.

(Refer Slide Time: 00:52)

So, let R be a region in xy plane, then number 1. If f of xy equals to 1 then the double integral over the region R $dx dy$ gives the area of region R . Number 2, if z equals to f of xy be a surface, then double integral over region R z of $dx dy$.

So, what we can do? Z is a function of x and y so, we can replace the z with that function, f of $x y$ $dx dy$ gives the volume of the region bounded by the surface z , and above xy plane. Number 3, if f of xy equals to ρ of xy be the density ; density means mass per unit area of the region R , then double integral over R f of xy or ρ of xy $dx dy$ gives the not total mass of region R ok.

So, if $f(x, y)$ equals to $\rho(x, y)$ that is the density function, then \bar{x} equals to $\frac{1}{M}$ upon M ; where M is the mass of the region R .

(Refer Slide Time: 05:13)

Applications of double integral

- 1 If $f(x, y) = 1$, then $\iint_R dx dy$ gives the area A of the region R .
- 2 If $z = f(x, y)$ is a surface, then $\iint_R f(x, y) dx dy$ gives the volume of the region beneath the surface $z = f(x, y)$ and above the $x - y$ plane.
- 3 If $f(x, y) = \rho(x, y)$ is a density function (mass per unit area) of a distribution of mass function in the $x - y$ plane, then $\iint_R f(x, y) dx dy$ gives the mass of R .
- 4 If $f(x, y) = \rho(x, y)$ is a density function, then

$$\bar{x} = \frac{1}{M} \iint_R x f(x, y) dx dy; \quad \bar{y} = \frac{1}{M} \iint_R y f(x, y) dx dy;$$
 give the coordinates of the center of gravity \bar{x}, \bar{y} of the mass M in R .

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 2

Double integral over R x times f of x, y $dx dy$ and \bar{y} equals to $\frac{1}{M}$ double integral over region R y times f of x, y $dx dy$ gives the coordinates of the center of gravity that is \bar{x}, \bar{y} of the mass M in R . If f of x, y is ρ , x, y is a density function, then I_x equals to double integral over the region R y^2 f of x, y $dx dy$, and I_y equals to double integral over R x^2 f of x, y $dx dy$, give the moment of inertia of the mass in R about the x axis.

(Refer Slide Time: 05:40)

Applications of double integral

1 If $f(x, y) = \rho(x, y)$ is a density function, then

$$I_x = \iint_R y^2 f(x, y) dx dy; \quad I_y = \iint_R x^2 f(x, y) dx dy$$

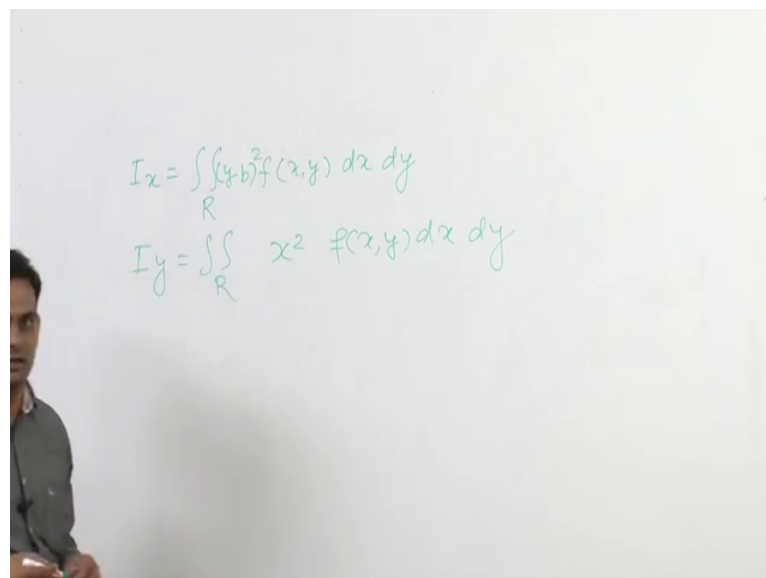

give the moment of inertia of the mass in R about the x -axis and y -axis, respectively. Here $I_0 = I_x + I_y$ is called the moment of inertia of the mass in R about the origin.

KT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 3

So, this is about x axis, and about the y axis this one. If I_0 is I_x plus I_y , then we say that moment of inertia of the mass R about the origin.

If I want to find out, the moment of inertia about a line let us say x equals to a , then it will become I_x over R .

(Refer Slide Time: 06:35)

So, it will remain y square f of x, y $dx dy$ and then I_y will become R x minus a whole square f of x, y $dx dy$. So, here you can see that this is the moment of inertia about the line x equals to a . If I want to find out the moment of inertia about a line y equals to b .

So, there will be no change in I_y ; however, this term will become y minus b whole square.

(Refer Slide Time: 07:36)

Ex. 1: The cylinder $x^2 + z^2 = 1$ is cut by the plane $x=0, y=0$ and $y=x$. Find the volume of the region in first octant.

Solⁿ: In the first octant, the equation of cylinder $z = \sqrt{1-x^2}$

$$V = \iiint_R z \, dx \, dy = \int_0^1 \int_0^x \sqrt{1-x^2} \, dy \, dx$$

$$= \int_0^1 x \sqrt{1-x^2} \, dx = \frac{1}{2} \int_0^{\pi/2} (\sin \theta) (\cos \theta)^{2 \cdot \frac{1}{2}} \, d\theta$$

Let $x = \sin \theta$
 $dx = \cos \theta \, d\theta$

$$= \frac{1}{2} \beta\left(1, \frac{3}{2}\right) = \frac{1}{2} \frac{\Gamma(1) \Gamma(\frac{3}{2})}{\Gamma(\frac{5}{2})} = \frac{1}{2} \frac{1 \cdot \frac{\sqrt{\pi}}{2}}{\frac{3\sqrt{\pi}}{4}} = \frac{1}{2} \cdot \frac{2}{3} = \frac{1}{3}$$

Now, we will take some example based on these formulas with just I have introduced to you. So, the example one is the cylinder x square plus z square equals to 1 is cut by the plane x equals to 0 y equals to 0 and y equals to x . So, this is the cylinder so, this will be the along y axis a cylinder of radius 1, and it is cut by the these 3 planes, x equals to 0 y equals to 0 and y equals to x . Find the volume of the region in first octant.

So, let us find the answer of this question. So, it is given that, we have to find a volume of the region only in first octant. So, in the first octant, the equation of the cylinder can be written as z equals to square root 1 minus x square ok. Now volume is given by the formula $z \, dx \, dy$ over a region R . So, the projection of this region this particular region in the xy plane will be something like this. So, z will be square root 1 minus x square. So, y will be 0 to x y equals to x and y equals to 0 and in the xy plane where z equals to 0 x will go from 0 to 1, and then $dx \, dy$

So, this will become so, only thing I made a $dy \, dx$ because these are the limits for x . So, it will become 0 to 1, and then I will integrate this with respect to y . So, y will come so, it will become x square root 1 minus x square dx . So, let x equals to $\sin \theta$, then dx will become $\cos \theta \, d\theta$. So, this way integral will convert 0 to π by 2, because when x is one, θ will become π by 2 x is $\sin \theta$, this will be 1 minus \sin square θ \cos

square theta square root will be cos theta and cos theta. So, sin theta cos square theta d theta ok.

So now I will show you that here for solving this we can use, the definition of beta and gamma functions, this I can write 1 by 2 into 2 times this one. Now this is sin theta so, this I can write sin theta raised to power 2 into 1 by 2 minus 1 2 into 1 minus 1. And this I can write cos theta square.

So, this I can write cos theta raised to power 2 3 by 2 minus 1. So, by the formula that beta of xy equals to 2 times integral 0 to pi by 2, sin theta raised to power 2 x minus 1 into cos theta raised to power 2 minus 1 d theta. The same thing we can see here x is 1 y is 3 by 2. So, this will become 1 by 2 beta of 1 3 by 2. This will become 1 by 2 gamma 1, gamma 3 by 2 upon gamma M plus 1. So, gamma pi by 2, this will be 1 by 2 1 by 2 gamma 1 by 2 upon 3 by 2 1 by 2 gamma 1 by 2 ; so, these 2 things will be canceled out. So, answer is 1 by 3.

So, in this way we can do this particular example. Another example I am taking here from the center of gravity. So, find the coordinates of the center of gravity of a plate.

(Refer Slide Time: 14:06)

Examples

Example-II

Find the coordinates of the centre of gravity of a plate whose density is constant and is bounded by the curve $y = x^2$ and $y = x + 2$.

Solution

Here, Mass $M = \iint_R k dx dy = k \int_{-1}^2 \int_{x^2}^{x+2} dy dx = \frac{9}{2}k$

The coordinates of the centre of gravity \bar{x}, \bar{y} are given as

$$\bar{x} = (2/9k) \iint_R kx dx dy = \frac{1}{2}$$

$$\bar{y} = (2/9k) \iint_R ky dx dy = \frac{8}{5}$$

IT ROORKEE
 NITEL ONLINE CERTIFICATION COURSE
 6

So, please note here it is a plate.

(Refer Slide Time: 14:24)

Solⁿ: density = k

$$M = \int_{-1}^2 \int_{x^2}^{x+2} k \, dy \, dx$$

$$= k \int_{-1}^2 (x+2-x^2) \, dx = \frac{9}{2} k$$

$$\bar{x} = \frac{1}{M} \iint_R x \, k \, dx \, dy$$

$$= \frac{2k}{9k} \int_{-1}^2 \int_{x^2}^{x+2} x \, dy \, dx = \frac{1}{2} \quad \left(\frac{1}{2}, \frac{8}{5}\right) \text{ Ans.}$$

$$\bar{y} = \frac{1}{M} \iint_R y \, k \, dx \, dy = \frac{2k}{9k} \int_{-1}^2 \int_{x^2}^{x+2} y \, dy \, dx = \frac{8}{5}$$

The graph shows a Cartesian coordinate system with x and y axes. A parabola $y = x^2$ and a straight line $y = x + 2$ are plotted. The region between them from $x = -1$ to $x = 2$ is shaded. The intersection points are labeled $(-1, 1)$ and $(2, 4)$. The center of mass is marked at $(\frac{1}{2}, \frac{8}{5})$.

So, 2-dimensional region, whose density is constant, let us say k and is bounded by the curve y equals to x square and y equals to x plus 2. So, the plate is like this x y . So, y equals to x square, and the other one is y equals to x plus 2. So, it will cut 1 2, 1 2. So, the region is this one. So, we have to find out the moment of inertia of this plate when the density is constant. So, it will intersect at this point; which will be minus 1 and 1 and this point will become 2 and 4.

So, first of all for finding the coordinates or moment of inertia we need to calculate mass. So, mass will be let us say M , M will become k , let us say density is k which is a constant $dy \, dx$. Here y lower limit is x square if I take a this kind of strip, vertical strip, and the upper limit is x plus 2. While the limit for x is minus 1 to 2. So, this will become minus 1 to 2 k I will take out. So, y so, it will become x plus 2 minus x square dx . And this will come out as 9 by 2 times k .

Now, we need to find out the coordinates of center of gravity. So, \bar{x} is given as 1 upon M integral over region R . R is this plate, and then x times density density is $k \, dx \, dy$. So, this equals to M is 9 by 2 k . So, 2 upon 9 k one k is here. So, this k I can take out, again limit will be minus 1 to 2 x square 2 x plus 2, and then x times $dy \, dx$, and this comes out to be 1 by 2 after solving this.

Similarly, \bar{y} is given by $\frac{1}{M} \int \int_R y k \, dx \, dy$. So, this will be again $\frac{2k}{9k} \int_0^1 (1-2x^2) 2x \, dx$. And after solving this it will come $\frac{8}{5}$. So, hence answer is $\frac{1}{2}$ and $\frac{8}{5}$ ok.

So, we have taken two examples one for volume, another one for center of gravity. Now, we will talk about the application of triple integral ok; so, in case of triple integral first of all more mass. So, the mass of a region Ω so now, Ω is a volumetric region 3-dimensional region, that is given by the triple integral over the region Ω $\rho(x,y,z) \, dx \, dy \, dz$.

(Refer Slide Time: 19:18)

Applications of triple integral

Evaluation of Mass

The mass of a region Ω is given by the triple integral

$$\text{Mass} = \int \int \int_{\Omega} \rho(x, y, z) \, dx \, dy \, dz$$

where $\rho(x, y)$ is the density at point (x, y) , Ω is the region.

IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 8

Where $\rho(x,y)$ is the density at a point x,y and Ω is the region. So, for the application of triple integral let us take this example.

(Refer Slide Time: 19:45)

Examples: Applications of triple integral

Example-I
 Find the mass of a uniform solid that is bounded by the regions $x^2 + y^2 = 2x$, $z = \sqrt{x^2 + y^2}$ and $z = 0$, with the assumption of constant density δ .

Solution
 Using polar co-ordinates let $x = r \cos \theta$, $y = r \sin \theta$, we get $0 \leq r \leq 2 \cos \theta$.
 Hence the mass becomes,

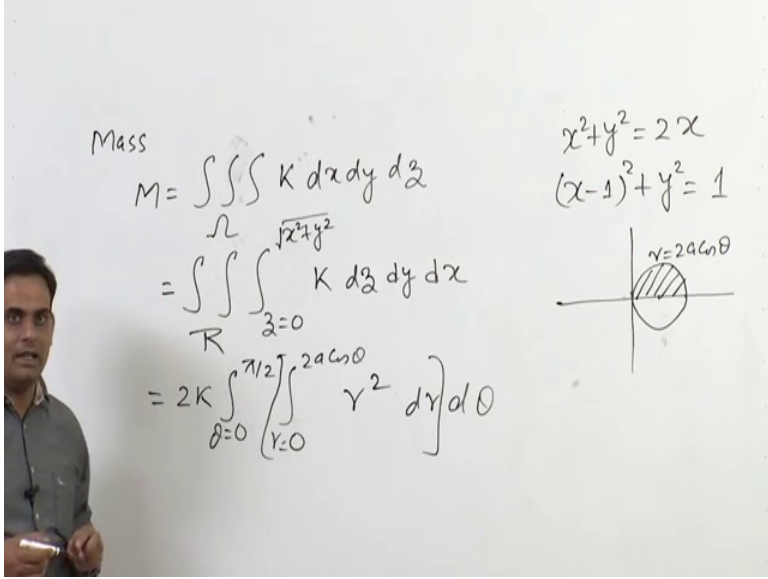

$$\text{Mass} = 2\delta \int_0^{\pi/2} \int_0^{2\cos\theta} \left(\int_0^{\sqrt{x^2+y^2}} dz \right) r dr d\theta$$

So, find the mass of a uniform solid that is bounded by the region $x^2 + y^2 = 2x$, $z = \sqrt{x^2 + y^2}$, and $z = 0$ with the assumption of constant density δ . So, let us try to find out the way how to solve this example.

So, here I need to find out mass.

(Refer Slide Time: 20:13)

$$\begin{aligned} \text{Mass} \\ M &= \iiint_{\Omega} K \, dx \, dy \, dz \\ &= \iiint_{\mathcal{R}} \int_0^{\sqrt{x^2+y^2}} K \, dz \, dy \, dx \\ &= 2K \int_{\theta=0}^{\pi/2} \int_{r=0}^{2a\cos\theta} r^2 \, dr \, d\theta \end{aligned}$$

$$\begin{aligned} x^2 + y^2 &= 2x \\ (x-1)^2 + y^2 &= 1 \\ r &= 2a\cos\theta \end{aligned}$$

So, mass will be M equals to the region Ω triple integral over region Ω , density let us say that is the constant. So, I will take k and then $dx \, dy \, dz$. Now, region is

something like that. Z is given equals to 0 to square root of x square plus y square, and then a region R ; which is given as x square plus y square equals to $2x$ and then k times $dx dy dz$; So, that I will take inside. So, $dz dy dx$, now the region is given as x square plus y square equals to $2x$. So, it means x minus 1 whole square plus y square equals to 1. So, it will be a circle having center at 1 and 0 and having radius 1. So, it will be a circle like this.

So, whatever mass we will be having above a x axis the same mass I will be having below. So, what I can do? I can write is $2k$. So, k I have taken out, and now I will concentrate on this region only. So, if I change it in polar coordinate, this curve will be R equals to $2a \cos \theta$. So, my (Refer Time: 22:29) will start from R equals to 0 and it will end on the curve R equals to $2a \cos \theta$ and θ will move from 0 to π by 2.

So, it is $2k$ 0 to π by 2 and then 0 to $2a \cos \theta$. So, these are limit for R these are the limits for θ , and then square root x square plus y square will become R and $dy dx$ or $dx dy$ will be $R dr d\theta$. So, basically it will become r square $dr d\theta$. So, first solve this one, and then you can solve for θ .

So, this is the way of handling this particular example. Now, another application of triple integral in terms of center of gravity or center of mass sometime because both are the same thing. So, center of gravity of a solid is given by the coordinates \bar{x} \bar{y} \bar{z} , where \bar{x} is given as 1 upon mass.

(Refer Slide Time: 23:46)

Applications of triple integral

Centre of Gravity

Centre of Gravity/Mass of a solid is given by the co-ordinates $(\bar{x}, \bar{y}, \bar{z})$, where

$$\bar{x} = \frac{1}{\text{Mass}} \int \int \int_V x \rho(x, y, z) \cdot dx dy dz$$

$$\bar{y} = \frac{1}{\text{Mass}} \int \int \int_V y \rho(x, y, z) \cdot dx dy dz$$

$$\bar{z} = \frac{1}{\text{Mass}} \int \int \int_V z \rho(x, y, z) \cdot dx dy dz$$

Note: The centre of mass will be about the axis of symmetry if the density is constant.

NPTEL ONLINE
CERTIFICATION COURSE

10

Triple integral over the region v , x times rho xy $dx dy dz$, here rho xy is the density. Similarly, for y bar just replace this x by y , an $in-z$ bar just replace this y by z ok. So, in this way we can calculate x bar y bar z bar, and please note here we need to calculate mass; For calculating the center of gravity or center of mass.

One more remark, I would like to mention here, the center of mass will be about the axis of symmetry, if the density is constant. So, this is the example find the z coordinates of the center of gravity of the hemisphere of radius a ok.

(Refer Slide Time: 24:34)

Applications of triple integral

Example-II
Find the z - coordinate of the centre of gravity of the hemisphere of radius a , i.e., $x^2 + y^2 + z^2 = a^2, z \geq 0$

Solution
Here, $\bar{z} = \frac{1}{\text{Mass}} \int \int \int_V z \rho(x, y) \cdot dx dy dz$, let density be k , then Mass

$$M = \int \int \int_V k dx dy dz = k \int_0^{2\pi} \int_0^{\pi/2} \int_0^a \rho^2 \sin(\phi) d\rho d\phi d\theta = \frac{2\pi k a^3}{3}$$

$$\bar{z} = (1/M) \int \int \int_V k z dx dy dz = \frac{3}{2\pi k a^3} \int \int \int_V k \rho \cos(\phi) \rho^2 \sin(\phi) d\rho d\phi d\theta = \frac{3a}{2}$$

 IIT ROORKEE NPTEL ONLINE CERTIFICATION COURSE

11

So, it is hemisphere so, above xy plane and give of radius a and I need to find out z coordinate of this. So, let us try to do it so, x square plus y square plus z square equals to a square, and z is greater than equals to 0.

(Refer Slide Time: 25:00)

The whiteboard shows the following derivations:

Solⁿ
Mass = $\iiint_{\Omega} k \, dx \, dy \, dz$
 $= k \int_{\phi=0}^{\pi/2} \int_{\theta=0}^{2\pi} \int_{\rho=0}^a \rho^2 \sin \phi \, d\rho \, d\theta \, d\phi$
 $= \frac{2\pi k a^3}{3}$

$\bar{z} = \frac{1}{M} \iiint_{\Omega} k z \, dx \, dy \, dz$
 $= \frac{3a}{2}$

On the right side of the board, the region is defined by:
 $x^2 + y^2 + z^2 = a^2$
 $z \geq 0$
 $0 \leq \theta \leq 2\pi$
 $0 \leq \phi \leq \pi/2$

So, basically first of all we need to calculate the mass, and then we will calculate the z coordinate of the center of gravity. So, the idea is mass will be so, density is constant here $dx \, dy \, dz$. Now, if I use the Cartesian coordinates here, the things will become quite complicated; because z will become 0 to square root of a square minus x square minus y square and so on.

So, let us find out there the simple way and we will change it into a spherical coordinates. So, spherical coordinates will be x equals to rho sin phi, and then rho cost phi. And after that $dx \, dy \, dz$ will be rho square sin phi d rho d phi d theta. We have seen prove this in some previous lecture in change of variables lecture.

So, hence and the limit will be theta will go for a circle if fair 0 to 2 pi, and for the complete if fair phi will go 0 to pi, but since it is a hemisphere. So now, my phi will go from 0 to pi by 2. So, mass will become 0 to pi by 2 k times, then I am having 0 to 2 pi that is 4 phi this is 4 theta, and then R will because radius is a. So, 0 to a $dx \, dy$; So, rho square sin phi d rho d phi d theta.

So, after solving it sorry d theta d phi, because we have written integral in this order; So, after solving it we got it 2 pi k a cube upon 3. Moreover, we need to calculate z coordinates of the center of gravity. So, it is given by 1 over M integral over the region R v, omega, sorry I have taken omega k times z into $dx \, dy$. So, again change everything in

polar coordinates sorry spherical coordinates and then solve it. So, it will come out as 3 a by 2.

Similarly, you can calculate the x bar and y bar also in x bar here we will be having x in y bar, here we will be having y. Now, another application of triple integral is moment of inertia.

(Refer Slide Time: 29:21)

The slide is titled "Applications of triple integral" and has a sub-heading "Moment of Inertia". It lists three formulas for the moment of inertia about the x, y, and z axes, each involving a triple integral over a region Ω of the density function $\rho(x, y, z)$ multiplied by the square of the distance from the axis to the point (x, y, z) .

Moment of Inertia

Moment of inertia about the x-axis:

$$I_x = \iiint_{\Omega} (y^2 + z^2) \rho(x, y, z) \, dx \, dy \, dz$$

Moment of inertia about the y-axis:

$$I_y = \iiint_{\Omega} (x^2 + z^2) \rho(x, y, z) \, dx \, dy \, dz$$

Moment of inertia about the z-axis:

$$I_z = \iiint_{\Omega} (y^2 + x^2) \rho(x, y, z) \, dx \, dy \, dz$$

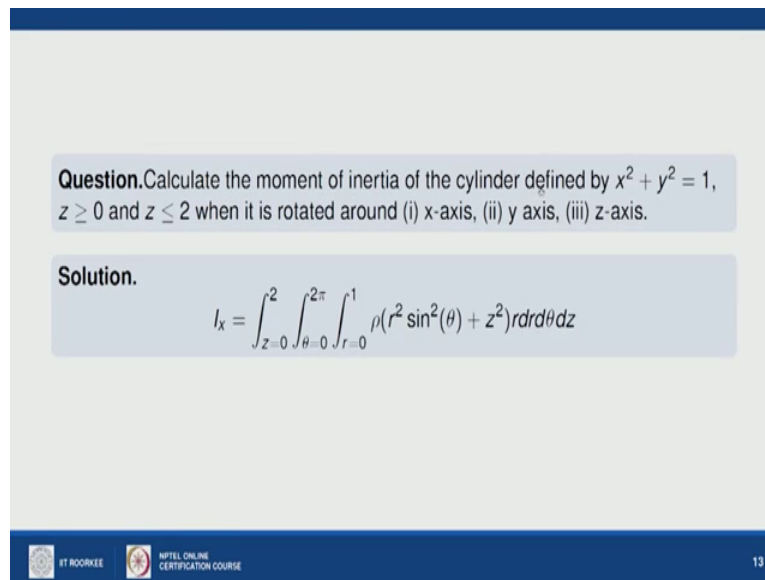

At the bottom of the slide, there are logos for "IIT ROORKEE" and "NPTEL ONLINE CERTIFICATION COURSE", and the page number "12".

So, the moment of inertia about the x axis is given by I_x equals to triple integral over the region Ω , $y^2 + z^2$ into density into $dx \, dy \, dz$.

Similarly, moment of inertia about y axis is I_y triple integral over Ω $x^2 + z^2$ into density function $dx \, dy \, dz$. Similarly, the moment of inertia about the z axis is given by I_z triple integral over Ω , $y^2 + x^2$ into density function $dx \, dy \, dz$.

So, for example, if we are having this one, calculate the moment of inertia of a cylinder define $x^2 + y^2 = 1$, z is greater than equals to 0, and z is less than equals to 2, when it is rotated around x axis, y axis and z axis

(Refer Slide Time: 30:05)

Question. Calculate the moment of inertia of the cylinder defined by $x^2 + y^2 = 1$, $z \geq 0$ and $z \leq 2$ when it is rotated around (i) x-axis, (ii) y axis, (iii) z-axis.

Solution.

$$I_x = \int_{z=0}^2 \int_{\theta=0}^{2\pi} \int_{r=0}^1 \rho(r^2 \sin^2(\theta) + z^2) r dr d\theta dz$$

IT ROORKEE NPTEL ONLINE CERTIFICATION COURSE 13

So, moment of inertia about x axis I_x is given by; so, z is given 0 to 2. Now $x^2 + y^2 = 1$. So, this is the cylinder of radius 1 along z axis. So, on the xy plane the projection of this cylinder will be circle of unit radius. So, we can change it in 2 polar coordinates so, θ will move from 0 to 2π and r will move from 0 to 1 $\rho = r^2 \sin^2 \theta + z^2$ $r dr d\theta dz$.

So, we are using here cylindrical coordinates. $\rho = r^2 \sin^2 \theta$ for y and z will be a such density and $dx dy dz$ will become $r dr d\theta dz$. So, by solving this we will calculate I_x , if I need to calculate I_y , only change will be this $\sin^2 \theta$ will become $\cos^2 \theta$. Because, it will be $x^2 + z^2$ so, x will be $R \cos \theta$ and if I need to find out I_z will be $r^2 \sin^2 \theta + r^2 \cos^2 \theta$. So, r^2 I will take common. So, it will become $\rho = r^2$ $r dr d\theta dz$. So, in this way we will solve this particular example.

So, in the brief summary of this lecture, I have introduced the applications of double integral, and triple integral, the applications were basically finding the area finding the volume, finding the mass of a region, finding the coordinates of center of gravity and then finally, finding the moment of inertia about a given line. So, with this I will end this lecture.

And, thank you very much.
