LECTURE 12

Recap: KUTTA-ZHUKHONSKY THEOREM
 $L = \rho U \Gamma$

Today: INTRODUCTION TO CONFORMAL TRANSFORMATION

CONFORMAL TRANSFORMATION

A technique used to transform simple shapes & flow patterns into more complicated ones & vice-versa.

$\zeta = f(z)$

z-plane \rightarrow ζ -plane

Transformations of this type $\zeta = f(z)$ which can be useful in obtaining solⁿ to difficult or complex geometries quite easily.

2D irrotational flows: $\nabla^2 \phi = 0$ & $\nabla^2 \psi = 0$
 where $\nabla^2 = \text{Laplacian operator}$
 $= \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$

So, in the previous lecture, we came across the Kutta-Zhukhovskiy theorem, which defines the lift force per unit depth in terms of the circulation. So, we said lift is $\rho U \Gamma$, and we proved this for a simple case of flow past a circular cylinder, and we did it two ways. One was essentially integrating the pressure distribution and the second was using the Blasius theorem.

So, in today's lecture, I will talk about another important technique, which is called as conformal transformation, and how this can help us obtain a variety of flows in much more complex scenarios. So, let us begin our lecture today. So, we will talk about conformal transformation. And what is conformal transformation first of all, so, this is a technique which is used to transform simple shapes or flow patterns into much more complicated ones and vice versa.

So, this is a technique which is used to transform you can say simple shapes and flow patterns into more complicated ones and we can do this vice versa. So, it can even be that we can go from a more complicated problem to a simpler one. But essentially it is more commonly used where we have a simple solution or a simple problem and we want to use that to derive a solution to a much more complex problem.

So, the way this works is, let me start with a simple case say we have a shape in the z plane or the z plane say this is a z plane and we have some complex shape in this plane. The solution to which we may not know or may know it either way, let us say we do not know the solution to this problem. But we know the solution to a simpler problem. For instance, we know the solution to say a problem which has a simpler geometry, say a circular geometry.

And this is what I am going to call as a ζ plane which has its axis as ξ and η . So, conformal transformation is about finding a suitable function, which says ζ to be f of z , which transforms this function or this type of an object to a shape of this type, or even vice versa where maybe we have the particular problem, which we know the solution to an easier to solve problem and you want to transform it back into a much more complicated shape.

So, what we are looking for are these transformations of this type. Let me write this down. So, we are looking for transformations of this type which I have written as ζ equal to f of z or f of z , which can be useful in obtaining solutions to difficult or complex geometries quite easily. So, you can imagine that if I have the solution to maybe the right problem, I can use a conformal transformation.

And I will talk about a little more about informal transformation very soon, but I could use some kind of transformation to revert or to bring it into a more complex scenario. Now, because this is transforming, not just the geometry, the flow will also have to transform and we are dealing with 2d irrotational flows.

We are dealing with 2d irrotational flows, which satisfy the equations $\nabla^2 \phi = 0$ and $\nabla^2 \psi = 0$ where ∇^2 is called as a Laplacian operator and it is given as say in this z plane this would be $d^2 dx^2 + d^2 dy^2$. So, we need to identify for instance, if we have a flow and a shape in the z plane and we do a conformal transformation and take it into the ζ plane then how does a geometry get transformed and how does a flow get transformed and the flow parameters are basically ϕ and ψ .

(Refer Slide Time: 06:30)

2D irrotational flows: $\nabla^2 \phi = 0$ & $\nabla^2 \psi = 0$
 where $\nabla^2 = \text{Laplacian operator}$
 $= \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$

Identify how streamfunction and velocity potential in one plane (say z -plane) transform to ζ -plane while still obeying conditions of irrotationality.

$$\frac{\partial \phi}{\partial x} = \frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial x} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial x} \quad \text{--- (1)}$$

$$\frac{\partial \phi}{\partial y} = \frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial y} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial y} \quad \text{--- (2)}$$

$\zeta = f(z)$

z-plane \rightarrow ζ -plane

Transformations of this type $\zeta = f(z)$ which can be useful in obtaining solⁿ to difficult or complex geometries quite easily.

2D irrotational flows: $\nabla^2 \phi = 0$ & $\nabla^2 \psi = 0$
 where $\nabla^2 = \text{Laplacian operator}$
 $= \frac{\partial^2}{\partial x^2} + \frac{\partial^2}{\partial y^2}$

$z = x + iy$
 $(x, y) \rightarrow (\xi, \eta)$

So, we need to identify how these stream function and the velocity potential in say one plane for instance for my case says z plane or z plane how these transform to the ζ plane while still obeying, which is the most important part, conditions of irrotationality. So, you want the

same rules to be still applicable irrespective of the fact that we are transforming the given problem.

So, what we need to check for whether the function in a specific problem let us say z problem, when it goes to zeta problem, it still satisfies the condition of irrationality is to check for how the Laplacian operator transforms when we go from the z plane to the zeta plane. So, we would need the following. So, we would need to calculate $d^2 \phi dx^2$ and $d^2 \phi dy^2$, and similarly, $d^2 \psi dx^2$ and $d^2 \psi dy^2$.

And we need to transform that to the zeta plane. For that you will need to calculate these derivatives for instance $d \phi dx$ because I know the second derivative of ϕ with respect to x will give me $d^2 \phi dx^2$, which is an essential component of the first part of the Laplacian operator. So, $d \phi dx$ for instance, would be if I use a chain rule, now, recall that our system is getting transformed we are going from z to ζ .

So, we will have $d \phi dx$ to be $d \phi d \xi d \xi dx$ plus $d \phi d \eta d \eta dx$. So, this is equation 1 for our case. And similarly, I can write $d \phi dy$, just the first derivatives for now, this will become $d \phi d \xi d \xi dy$ plus $d \phi d \eta d \eta dy$ and say this is equation 2. This is just by a chain rule. Essentially what I am doing is if you look at this problem, we have ζ is f of z , z is a number in the complex plane which is x plus iy , we are transforming it to the zeta plane. So, that when we go to the zeta plane x comma y changes to ξ comma η , we get new coordinate ξ and η .

(Refer Slide Time: 10:04)

The image shows a handwritten derivation in a Notepad window titled "Note1 - Windows Journal". The derivation calculates the second derivative of a function ϕ with respect to x in terms of derivatives with respect to ξ and η . The steps are as follows:

$$\frac{\partial^2 \phi}{\partial x^2} = \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial x} \right) = \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial x} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial x} \right)$$

$$= \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial x} \right) + \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial x} \right)$$

Using the chain rule, the first term is expanded:

$$\frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial x} \right) = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial x^2} + \frac{\partial \xi}{\partial x} \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \xi} \right)$$

The second term is also expanded:

$$= \frac{\partial \phi}{\partial \eta} \frac{\partial^2 \eta}{\partial x^2} + \frac{\partial \eta}{\partial x} \left[\frac{\partial \xi}{\partial x} \frac{\partial \phi}{\partial \xi} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial x} \right]$$

Combining these results, the final expression is:

$$\frac{\partial^2 \phi}{\partial x^2} = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial x^2} + \left(\frac{\partial \xi}{\partial x} \right)^2 \frac{\partial^2 \phi}{\partial \xi^2} + \left(\frac{\partial \xi}{\partial x} \right) \left(\frac{\partial \eta}{\partial x} \right) \frac{\partial^2 \phi}{\partial \xi \partial \eta} \quad \text{--- (3)}$$

Additional notes in the image include "Chain rule" and a small diagram showing the relationship between $\frac{\partial^2 \phi}{\partial x^2}$ and $\frac{\partial^2 \phi}{\partial \xi^2}$.

$$\frac{\partial}{\partial z} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial z} \right) = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial z^2} + \frac{\partial \xi}{\partial z} \frac{\partial}{\partial z} \left(\frac{\partial \phi}{\partial \xi} \right)$$

Chain rule:
 $\frac{\partial \phi}{\partial z} = \frac{\partial}{\partial \xi} \left(\frac{\partial \phi}{\partial z} \right)$
 $= \frac{\partial \phi}{\partial \xi}$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial z^2} + \frac{\partial \xi}{\partial z} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial z} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial z} \right)$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial z^2} + \frac{\partial \xi}{\partial z} \left[\frac{\partial \xi}{\partial z} \frac{\partial \phi}{\partial \xi} + \frac{\partial \xi}{\partial \eta} \frac{\partial \phi}{\partial \eta} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial z} \right]$$

$$\frac{\partial}{\partial z} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial z} \right) = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial z^2} + \left(\frac{\partial \xi}{\partial z} \right)^2 \frac{\partial \phi}{\partial \xi} + \left(\frac{\partial \xi}{\partial \eta} \right) \left(\frac{\partial \eta}{\partial z} \right) \frac{\partial \phi}{\partial \eta} \quad \text{--- (3)}$$

$$\frac{\partial \phi}{\partial \eta} \rightarrow \frac{\partial}{\partial \eta} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial \eta} \right) = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} + \frac{\partial \xi}{\partial \eta} \frac{\partial}{\partial \eta} \left(\frac{\partial \phi}{\partial \xi} \right)$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} + \frac{\partial \xi}{\partial \eta} \frac{\partial}{\partial \eta} \left(\frac{\partial \phi}{\partial \xi} \right)$$

$$\frac{\partial \phi}{\partial x} = \frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial x} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial x} \quad \text{--- (1)}$$

$$\frac{\partial \phi}{\partial \eta} = \frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial \eta} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial \eta} \quad \text{--- (2)}$$

$$\frac{\partial^2 \phi}{\partial x^2} = \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial x} \right) = \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial x} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial x} \right)$$

$$= \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial x} \right) + \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial x} \right)$$

$$\frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial x} \right) = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial x^2} + \frac{\partial \xi}{\partial x} \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \xi} \right)$$

Chain rule:
 $\frac{\partial \phi}{\partial x} = \frac{\partial}{\partial \xi} \left(\frac{\partial \phi}{\partial x} \right)$
 $= \frac{\partial \phi}{\partial \xi}$

Now, $d\phi/dy$ is also done. Now, what I am going to do is try and demonstrate how the Laplacian will change. So, say we want to calculate $d^2\phi/dx^2$, which would be d by dx of $d\phi/dx$. Now, this I am going to now use, I am going to use equation 1 to define what $d\phi/dx$ will be in terms of ξ and η . So, we can write this as d by dx of $d\phi/d\xi d\xi/dx$ plus $d\phi/d\eta d\eta/dx$.

Which we can also write as if we split the derivative into two parts, we could write this as d by dx of $d\phi/d\xi d\xi/dx$ plus d by dx of $d\phi/d\eta d\eta/dx$. I am hoping that you are with me till this point. Now, the process from here is slightly long, it is quite doable. But for the purpose of this demonstration, I am going to try and stick to some aspects only. Try and show you how certain terms evolve. And then I will sort of generalize in the end.

So, for now, let me just consider this part. Let us only focus on this part for now. So, say we would write this as $d \text{ by } dx \text{ of } d \text{ phi } d \text{ xi } d \text{ xi } dx$, I just want to look at how this will simplify. So, I can use a chain rule here. And the way I would use the chain rule is let us say we do the first we keep the first function constant, we do the derivative the second one, so we will get $d^2 \text{ xi } dx \text{ square plus}$, we will have $d \text{ xi } dx \text{ into } d \text{ by } dx \text{ of}$, we will get $d \text{ phi } d \text{ xi}$, this is just using the chain rule.

Now, what I am going to do is I see that there is the derivative of respect to phi or this term is essentially, if you want to put it, this would be $d^2 \text{ phi } dx \text{ d xi}$, which I could also write as $d \text{ by } d \text{ xi} \text{ of } d \text{ phi } dx$. And I could use $d \text{ phi } dx$, which I have in equation 1. So, $d \text{ phi } dx$ is given an equation 1. So, let us use this and simplify what we have on the right side. So, we will have $d \text{ phi } d \text{ xi } d^2 \text{ psi } dx \text{ square plus}$ we will have $d \text{ xi } dx$.

And now we will have $d \text{ by } d \text{ xi} \text{ of } d \text{ phi } dx$ which is $d \text{ phi } d \text{ xi } d \text{ xi } dx \text{ plus } d \text{ phi } d \text{ eta } d \text{ eta } dx$. This is just from equation 1. You can just verify. Now, we take the derivatives. So, we will have $d \text{ xi } dx$, so $d \text{ by } d \text{ xi}$ operated on the first function which is $d \text{ phi } d \text{ xi } d \text{ xi } dx$, so this will be $d \text{ xi } dx$, this would be $d \text{ phi } d \text{ xi } dx \text{ times } d^2 \text{ phi } d \text{ xi } \text{ square plus}$ if I go by chain rule we will have $d \text{ phi } d \text{ xi} \text{ into } d^2$. Let me write this down.

So, we can $d \text{ phi } d \text{ xi} \text{ into } d^2 \text{ psi } d \text{ xi } dx$, which is actually if you are if you notice carefully this should be 0 because $d \text{ xi}$ will be 1. So, this is going to be $d \text{ of a constant by } dx$ which is 1 or which is 0, plus we will have $d^2 \text{ phi } d \text{ xi } d \text{ eta } d \text{ eta } dx$. And finally, we will have another term, which would sort of go by $d \text{ by } d \text{ xi} \text{ of } d \text{ eta } dx$, but $e \text{ times } xi$ being independent variables, that term will also give you a 0.

So, finally, what we have is if we just now open up the brackets, we will have the following derivatives, this is what we will have for $d \text{ by } dx \text{ of } d \text{ phi } d \text{ xi } d \text{ xi } dx$. So, let me say this is equation 3. As you can see, it is growing now, for example, one term only in that $d^2 \text{ phi } dx \text{ square}$ gave me so many terms, we could do the other part as well. But let us now focus on $d^2 \text{ phi } dy \text{ square}$.

If I look at equation 2 now, where we have written $d \text{ phi } dy$, so $d^2 \text{ phi } dy \text{ square}$ will have the first function this one with $d \text{ by } dy$, and then this one with $d \text{ by } dy$. So, just for convenience, or for some variety, let me just say I will take this one with $d \text{ by } dy$. So, $d^2 \text{ phi } dy \text{ square}$ will lead me to, if I take this derivative, it will lead me to $d \text{ by } dy \text{ of}$, as I said the first term, which is $d \text{ phi } d \text{ xi } d \text{ xi } dy$. So, we will have $d \text{ phi } d \text{ xi } d \text{ xi } dy$.

So, let us see what this gives us. So, if I take these derivatives now, we will have $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2}$ and then we will have again $\frac{\partial}{\partial y} \left(\frac{\partial \phi}{\partial x} \right)$, where I again note that this is very similar to what I had here. It is the same idea that I can now swap the order of the derivatives, I can take the y derivative first and then the x derivative. So, I could write this as $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + \frac{\partial}{\partial y} \left(\frac{\partial \phi}{\partial x} \right)$ and then I use $\frac{\partial \phi}{\partial y}$ from equation 2.

(Refer Slide Time: 18:32)

The image shows a Notepad window with handwritten mathematical derivations. The first part, labeled (3), shows the expansion of the Laplacian of a scalar field ϕ with respect to x and y . The second part, labeled (4), shows the expansion of the mixed partial derivative $\frac{\partial}{\partial y} \left(\frac{\partial \phi}{\partial x} \right)$.

$$\frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial x} \right) = \frac{\partial^2 \phi}{\partial x^2} + \left(\frac{\partial \xi}{\partial x} \right)^2 \frac{\partial^2 \phi}{\partial \xi^2} + \left(\frac{\partial \xi}{\partial x} \right) \left(\frac{\partial \eta}{\partial x} \right) \frac{\partial^2 \phi}{\partial \xi \partial \eta} \quad \text{--- (3)}$$

$$\frac{\partial \phi}{\partial y} \rightarrow \frac{\partial}{\partial y} \left(\frac{\partial \phi}{\partial x} \right) = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial y^2} + \frac{\partial \xi}{\partial y} \frac{\partial}{\partial \xi} \left(\frac{\partial \phi}{\partial \xi} \right)$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial y^2} + \frac{\partial \xi}{\partial y} \frac{\partial}{\partial \xi} \left(\frac{\partial \phi}{\partial \xi} \right)$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial y^2} + \frac{\partial \xi}{\partial y} \left[\frac{\partial}{\partial \xi} \left(\frac{\partial \phi}{\partial \xi} \right) \frac{\partial \xi}{\partial y} + \frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial y} \right]$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial y^2} + \left(\frac{\partial \xi}{\partial y} \right)^2 \frac{\partial^2 \phi}{\partial \xi^2} + \left(\frac{\partial \xi}{\partial y} \right) \left(\frac{\partial \eta}{\partial y} \right) \frac{\partial^2 \phi}{\partial \xi \partial \eta} \quad \text{--- (4)}$$

So, we use $\frac{\partial \phi}{\partial y}$ from equation 2. So, we have $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} + \frac{\partial}{\partial y} \left(\frac{\partial \phi}{\partial x} \right)$ plus say $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2}$ which we can just take one more maybe a couple of steps to simplify so that some pattern emerges. So, we have $\frac{\partial^2 \phi}{\partial x^2}$, this will be say $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2}$ plus $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2}$. And which we can now collect together to get the following.

So, we will have $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2}$ plus $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2}$ into $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2}$. Say this is our fourth equation. So, you see that when I do this, we now have at least some parts of the picture, we have some derivative, we have calculated some derivative here we have determined this part of the derivative here, the only two terms that remain are essentially the following.

(Refer Slide Time: 20:27)

The screenshot shows a Notepad window with the following handwritten content:

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial y^2} + \left(\frac{\partial \xi}{\partial y} \right)^2 \frac{\partial^2 \phi}{\partial \xi^2} + \left(\frac{\partial \xi}{\partial y} \frac{\partial \eta}{\partial y} \right) \frac{\partial^2 \phi}{\partial \xi \partial \eta} \quad \text{--- (4)}$$

$$\frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial x} \right) = \frac{\partial \phi}{\partial \eta} \frac{\partial^2 \eta}{\partial x^2} + \left(\frac{\partial \eta}{\partial x} \right)^2 \frac{\partial^2 \phi}{\partial \eta^2} + \left(\frac{\partial \xi}{\partial x} \right) \left(\frac{\partial \eta}{\partial x} \right) \frac{\partial^2 \phi}{\partial \xi \partial \eta} \quad \text{--- (5)}$$

$$\frac{\partial}{\partial \eta} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial \eta} \right) = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} + \left(\frac{\partial \xi}{\partial \eta} \right)^2 \frac{\partial^2 \phi}{\partial \xi^2} + \left(\frac{\partial \xi}{\partial \eta} \right) \left(\frac{\partial \eta}{\partial \eta} \right) \frac{\partial^2 \phi}{\partial \xi \partial \eta} \quad \text{--- (6)}$$

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0$$

At the bottom left of the Notepad window, there is an NPTEL logo.

We have not done d by dx of d phi d eta d eta dx. But this is quite easy now, if I can write this for you straight away, this should be d phi d eta d2 eta dx square plus d eta dx square d2 phi d eta square plus we will have d xi dx d eta dx into d2 phi d eta d xi. So, this is the fifth term which will come from the d2 phi dx square, the second part of that expression.

And similarly, if you look at d2 phi dy square, this other term that I have not worked out yet is d by dy of d phi d eta d eta dy which again I can write as just to save some time, which I am sure you can work out now on your own, this will be d phi d eta d2 eta dy square plus d eta dy square d2 phi d eta square plus d xi dy d eta dy times d2 phi d xi d eta.

So, long derivation I understand but we have now assembled all parts to calculate what we said was d2 phi dx square plus d2 phi dy square equal to 0. So, we have now have everything in this equation in terms of xi and eta. So, what we can now do is assemble it.

So, let us assemble, let us put $d^2 \phi dx^2$ and then $d^2 \phi dy^2$. So, when I put $d^2 \phi dx^2$ now I want you to understand is some kind of a pattern that is developed now, when I write, for instance, the first expression here. This equation 3 will bring the first part of it. So, we will have terms of this type, we will have terms of this type and then this one, so we will have basically some terms which will have first derivatives of ϕ , but second derivatives of x or y .

We will have few terms which will have second derivatives of ϕ and then squares of the derivatives of x or y and then some kind of cross derivative terms. That is true in all expressions that you see here. First derivative multiplied by second derivative and then the derivative square multiplied by second derivative of ϕ and then cross derivatives. Same thing has happened here. So, you can see that it is the pattern will, there is some pattern to it at least.

(Refer Slide Time: 23:53)

Assemble eqns (3) - (6):

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = \frac{\partial^2 \phi}{\partial \xi^2} \left[\left(\frac{\partial \xi}{\partial x} \right)^2 + \left(\frac{\partial \xi}{\partial y} \right)^2 \right] + \frac{\partial^2 \phi}{\partial \eta^2} \left[\left(\frac{\partial \eta}{\partial x} \right)^2 + \left(\frac{\partial \eta}{\partial y} \right)^2 \right]$$

$$+ 2 \frac{\partial^2 \phi}{\partial \xi \partial \eta} \left[\frac{\partial \xi}{\partial x} \frac{\partial \eta}{\partial x} + \frac{\partial \xi}{\partial y} \frac{\partial \eta}{\partial y} \right] + \frac{\partial \phi}{\partial \xi} \left[\frac{\partial^2 \xi}{\partial x^2} + \frac{\partial^2 \xi}{\partial y^2} \right]$$

$$+ \frac{\partial \phi}{\partial \eta} \left[\frac{\partial^2 \eta}{\partial x^2} + \frac{\partial^2 \eta}{\partial y^2} \right] = 0 - (7)$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial x^2} + \frac{\partial \xi}{\partial x} \left[\frac{\partial^2 \phi}{\partial x^2} \frac{\partial \xi}{\partial \xi} + \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial x^2} + \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial x^2} \right]$$

$$\checkmark \frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial x} \right) = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial x^2} + \left(\frac{\partial \xi}{\partial x} \right)^2 \frac{\partial^2 \phi}{\partial x^2} + \frac{\partial \xi}{\partial x} \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial x^2} \quad \text{--- (3)}$$

$$\frac{\partial \phi}{\partial \eta} \rightarrow \frac{\partial}{\partial \eta} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial \eta} \right) = \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} + \frac{\partial \xi}{\partial \eta} \frac{\partial}{\partial \eta} \left(\frac{\partial \phi}{\partial \xi} \right)$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} + \frac{\partial \xi}{\partial \eta} \frac{\partial}{\partial \eta} \left(\frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial \eta} + \frac{\partial \phi}{\partial \xi} \frac{\partial \xi}{\partial \eta} \right)$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} + \frac{\partial \xi}{\partial \eta} \left[\frac{\partial^2 \phi}{\partial \xi^2} \frac{\partial \xi}{\partial \eta} + \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} \right]$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} + \frac{\partial \xi}{\partial \eta} \left[\frac{\partial^2 \phi}{\partial \xi^2} \frac{\partial \xi}{\partial \eta} + \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} \right]$$

$$= \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} + \left(\frac{\partial \xi}{\partial \eta} \right)^2 \frac{\partial^2 \phi}{\partial \xi^2} + \frac{\partial \xi}{\partial \eta} \frac{\partial \phi}{\partial \xi} \frac{\partial^2 \xi}{\partial \eta^2} \quad \text{--- (4)}$$

$$\frac{\partial}{\partial x} \left(\frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial x} \right) = \frac{\partial \phi}{\partial \eta} \frac{\partial^2 \eta}{\partial x^2} + \left(\frac{\partial \eta}{\partial x} \right)^2 \frac{\partial^2 \phi}{\partial \eta^2} + \frac{\partial \eta}{\partial x} \frac{\partial \phi}{\partial \eta} \frac{\partial^2 \eta}{\partial x^2} \quad \text{--- (5)}$$

$$\frac{\partial}{\partial \eta} \left(\frac{\partial \phi}{\partial \eta} \frac{\partial \eta}{\partial \eta} \right) = \frac{\partial \phi}{\partial \eta} \frac{\partial^2 \eta}{\partial \eta^2} + \left(\frac{\partial \eta}{\partial \eta} \right)^2 \frac{\partial^2 \phi}{\partial \eta^2} + \frac{\partial \eta}{\partial \eta} \frac{\partial \phi}{\partial \eta} \frac{\partial^2 \eta}{\partial \eta^2} \quad \text{--- (6)}$$

$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0$$

So, if you assemble everything now, all equations. So, if we assemble equations 3 to 6, we will have $d^2 \phi dx^2$ plus $d^2 \phi dy^2$ to be the following. We will have $d^2 \phi dx^2$ which comes from let me show you here $d^2 \phi dx^2$, which comes from here this middle term. So, we will have $d^2 \phi dx^2$ and similarly we will have $d^2 \phi dy^2$. Look at its coefficient it is dx^2 .

Similarly, we have another $d^2 \phi dx^2$, which will give me $dx^2 dy^2$ as a coefficient. So, we will say this is $d^2 \phi dx^2 dy^2$ plus $dx^2 dy^2$ that is 1 part. In a similar manner, we will have a $d^2 \phi dy^2$. So, let us look at this one, we will have $d^2 \phi dy^2$, which has coefficient here dy^2 and then we will have $dy^2 dx^2$. So, we can write that here.

So, we will have $d\eta dx^2 + d\eta dy^2$. Then we will have some cross derivative terms, which will add, so we will have $2 d^2\phi dx dy$. So, we can just compare where this came from. This is coming from here and here, each of these will have this same contribution. So, we have now seen that it is two of each type, so two of $d\eta dx^2$, and then two of $d\eta dy^2$. So, that is why we have a coefficient 2 here, which is justified.

And plus, now we will have single derivative terms, such as this one. Let us look at, this one, you have $d\phi dx^2 + d\psi dy^2$, and then we will have, similarly, we will have $d\phi dx dy$, for instance, $d^2\psi dx^2$. So, these terms will also now come together. So, we will have $d\phi dx^2 + d\psi dy^2 + d\phi dx dy + d\psi dx^2 + d\psi dy^2$ plus $d\phi dx^2 + d\psi dy^2$.

Now, this should be 0 because the left-hand side is 0, by transformation this is what we have obtained say this is equation 7.

\dots

NPTEL

Now, we talk about what was the nature of this transformation. Notice that the transformation that I have invoked is zeta is some f of z that was a transformation that we started with. Now, we say that this transformation is conformal. We said this is conformal if f of z is an analytic function. So, the transformation will be conformal or it would be called a conformal transformation if f of z is analytic. Now, note that f of z which is z being in the, in terms of x and y being x plus iy, this is being transformed to a new set of coordinates in this zeta plane, which I am writing it as xi of x comma y plus eta of x comma y.

So, if the function f of z is analytic, then the component is zeta the real and the imaginary part they must satisfy the Cauchy Riemann equation. So, for analyticity we know that xi x y and eta x y must satisfy the Cauchy Riemann equations, that is how we say our function is analytic. In fact, that is the whole premise of us using complex analysis in this course. Now,

what are the Cauchy Riemann equations for zeta or the components of zeta which are psi and eta.

The Cauchy Riemann equations here would be that $\frac{d\xi}{dx}$ must be the same as $\frac{d\eta}{dy}$ that is the first Cauchy Riemann equations. The second one is $\frac{d\xi}{dy}$ is minus $\frac{d\eta}{dx}$. If our transformation is such that it is analytic, then we call it as a conformal transformation. And for the transformation to be conformal, we need to have its real and imaginary parts satisfy the Cauchy Riemann equations.

Now, I can use this to say something about what I have derived in equation 7. So, for instance, if I invoke this equation here, the first identity, then I can take a second derivative of this with respect to x. So, I will have $\frac{d^2\xi}{dx^2}$ to be $\frac{d^2\eta}{dx dy}$. And if I take maybe a second derivative of this with respect to y, we will have $\frac{d^2\xi}{dy^2}$ to be minus $\frac{d^2\eta}{dx dy}$.

And I could merely add these two now, to get the $\frac{d^2\xi}{dx^2}$ plus $\frac{d^2\xi}{dy^2}$ is 0. So, for our function, which is an analytic function, $\frac{d^2\xi}{dx^2}$ plus $\frac{d^2\xi}{dy^2}$ is 0, which means we do not have this contribution showing up in this equation 7, this will go to 0. Similarly, I could have proven that $\frac{d^2\eta}{dx^2}$ plus $\frac{d^2\eta}{dy^2}$ is also 0.

That is again something that you can prove by taking, let us say derivative with respect to y of the first Cauchy Riemann equation and then derivative with respect to x of the second Cauchy Riemann equation, you will get the same identity. So, that means this is also going to 0.

(Refer Slide Time: 32:22)

$\Rightarrow \xi(x,y) \text{ \& } \eta(x,y) \text{ must satisfy C-R eqns.}$
C-R eqns. $\frac{\partial \xi}{\partial x} = \frac{\partial \eta}{\partial y} \quad \frac{\partial \xi}{\partial y} = -\frac{\partial \eta}{\partial x}$

$\frac{\partial^2 \xi}{\partial x^2} = \frac{\partial^2 \eta}{\partial x \partial y} \quad \frac{\partial^2 \xi}{\partial y^2} = -\frac{\partial^2 \eta}{\partial x \partial y}$
 $\frac{\partial^2 \xi}{\partial x^2} + \frac{\partial^2 \xi}{\partial y^2} = 0$
 $\frac{\partial^2 \eta}{\partial x^2} + \frac{\partial^2 \eta}{\partial y^2} = 0$
 $\frac{\partial \xi}{\partial x} \frac{\partial \eta}{\partial x} = -\frac{\partial \eta}{\partial y} \frac{\partial \xi}{\partial y} \quad \frac{\partial \xi}{\partial x} \frac{\partial \eta}{\partial x} + \frac{\partial \eta}{\partial y} \frac{\partial \xi}{\partial y} = 0$

Assemble eqns. (3) - (6):
 $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = \frac{\partial^2 \phi}{\partial \xi^2} \left[\left(\frac{\partial \xi}{\partial x} \right)^2 + \left(\frac{\partial \xi}{\partial y} \right)^2 \right] + \frac{\partial^2 \phi}{\partial \eta^2} \left[\left(\frac{\partial \eta}{\partial x} \right)^2 + \left(\frac{\partial \eta}{\partial y} \right)^2 \right]$
 $+ 2 \frac{\partial^2 \phi}{\partial \xi \partial \eta} \left[\frac{\partial \xi}{\partial x} \frac{\partial \eta}{\partial x} + \frac{\partial \xi}{\partial y} \frac{\partial \eta}{\partial y} \right] + \frac{\partial \phi}{\partial \xi} \left[\frac{\partial^2 \xi}{\partial x^2} + \frac{\partial^2 \xi}{\partial y^2} \right] + \frac{\partial \phi}{\partial \eta} \left[\frac{\partial^2 \eta}{\partial x^2} + \frac{\partial^2 \eta}{\partial y^2} \right] = 0 \quad (7)$

$\zeta = f(z)$ is CONFORMAL if $f(z)$ is analytic.
 Note: $\zeta = f(z) = f(x+iy) = \xi(x,y) + i\eta(x,y)$
 $\therefore \xi(x,y) \text{ \& } \eta(x,y) \text{ must satisfy C-R eqns.}$

Now, let us look at the other three terms left in this equation 7. To say something about them. Let us consider multiplying the two Cauchy Riemann identities. So, if I say these $d\xi dx$ times say $d\eta dx$, where I know that $d\xi dx$ is $d\eta dy$ and $d\eta dx$ is minus $d\xi dy$.

Now, notice that appears here in this coefficient of the mixed derivative. What we are saying is $d\xi dx d\eta dx$ plus $d\eta dy d\xi dy$ is 0. That simplifies my equation 7 because then this is also going to 0, the third term here is also gone now. Now, let us look at the last thing that remains, which is what about these coefficients? This and this what happens to them. Now, to understand how they transform how the change, let us take the squares of the Cauchy Riemann equation.

(Refer Slide Time: 33:47)

$$\frac{\partial^2 \eta}{\partial x^2} + \frac{\partial^2 \eta}{\partial y^2} = 0$$

$$\frac{\partial \xi}{\partial x} \frac{\partial \eta}{\partial x} = -\frac{\partial \eta}{\partial y} \frac{\partial \xi}{\partial y} \quad \frac{\partial \xi}{\partial x} \frac{\partial \eta}{\partial x} + \frac{\partial \eta}{\partial y} \frac{\partial \xi}{\partial y} = 0$$

$$\left(\frac{\partial \xi}{\partial x}\right)^2 = \left(\frac{\partial \eta}{\partial y}\right)^2 \quad \left(\frac{\partial \xi}{\partial y}\right)^2 = \left(\frac{\partial \eta}{\partial x}\right)^2$$

$$\left(\frac{\partial \xi}{\partial x}\right)^2 + \left(\frac{\partial \xi}{\partial y}\right)^2 = \left(\frac{\partial \eta}{\partial x}\right)^2 + \left(\frac{\partial \eta}{\partial y}\right)^2$$

$$\text{EQN } 7 \rightarrow 2 \left(\frac{\partial^2 \phi}{\partial \xi^2} + \frac{\partial^2 \phi}{\partial \eta^2} \right) \left(\left(\frac{\partial \xi}{\partial x}\right)^2 + \left(\frac{\partial \xi}{\partial y}\right)^2 \right) = 0$$

$$\left(\frac{\partial \xi}{\partial x}\right)^2 + \left(\frac{\partial \xi}{\partial y}\right)^2 = \left(\frac{\partial \eta}{\partial x}\right)^2 + \left(\frac{\partial \eta}{\partial y}\right)^2$$

$$\text{EQN } 7 \rightarrow 2 \left(\frac{\partial^2 \phi}{\partial \xi^2} + \frac{\partial^2 \phi}{\partial \eta^2} \right) \left(\left(\frac{\partial \xi}{\partial x}\right)^2 + \left(\frac{\partial \xi}{\partial y}\right)^2 \right) = 0$$

$$\frac{\partial^2 \phi}{\partial \xi^2} + \frac{\partial^2 \phi}{\partial \eta^2} = 0 \quad \text{Laplace eq. in } \xi\text{-plane.}$$

$$\frac{\partial^2 \psi}{\partial \xi^2} + \frac{\partial^2 \psi}{\partial \eta^2} = 0$$

So, I can say that $\frac{\partial^2 \xi}{\partial x^2}$ will be $\frac{\partial^2 \eta}{\partial y^2}$ and $\frac{\partial^2 \eta}{\partial y^2}$ will be $\frac{\partial^2 \xi}{\partial x^2}$. If I add these two equations, I will have $\frac{\partial^2 \xi}{\partial x^2} + \frac{\partial^2 \eta}{\partial y^2}$ to be the same as $\frac{\partial^2 \eta}{\partial x^2} + \frac{\partial^2 \xi}{\partial y^2}$. Using this now, if I look at equation 7, which had these squares as the coefficients, we can now write equation seven in the following way. We can now write the equation 7 is 2 times say $\frac{\partial^2 \phi}{\partial \xi^2} + \frac{\partial^2 \phi}{\partial \eta^2}$ times say $\frac{\partial^2 \xi}{\partial x^2} + \frac{\partial^2 \xi}{\partial y^2}$ is 0.

Now, I note that this cannot be 0 because it is definitely positive that is a sum of squares. And so, clearly $\frac{\partial^2 \phi}{\partial \xi^2} + \frac{\partial^2 \phi}{\partial \eta^2}$ must be 0. And now, this is basically the Laplace equation in the zeta plane. So, what we have now proved is that the Laplace

equation that we had in the z plane or z plane transforms to Laplace equation in the zeta plane.

And similarly, I could also prove that for the stream function we will have $d^2 \psi / dx^2 + d^2 \psi / dy^2 = 0$ that will also be the same basic derivation. So, that can also be proved now. So, we have a key message here now, and the message is since phi and psi satisfies the Laplace equation in both zeta and z plane. Hence, a complex potential which lets in z plane is also a valid complex potential in the zeta plane and vice versa.

(Refer Slide Time: 36:38)

The screenshot shows a Notepad window with the following handwritten content:

$$\frac{\partial^2 \psi}{\partial \xi^2} + \frac{\partial^2 \psi}{\partial \eta^2} = 0$$

A complex potential in the z-plane is also a valid complex potential in the ζ -plane.
 $\therefore \phi$ & ψ satisfy Laplace's eqn. in both z- & ζ -planes.
 $\zeta = f(z)$ is a CONFORMAL TRANSFORMATION.

Q. How does the complex velocity change due to this transformation?

$$W(z) = \frac{dF(z)}{dz} = \frac{dF}{d\zeta} \frac{d\zeta}{dz} = \underbrace{w(\zeta)}_{\text{Complex velocity in } \zeta\text{-plane}} \frac{d\zeta}{dz}$$

The NPTEL logo is visible in the bottom left corner of the Notepad window.

So, a complex potential in the z plane, a valid complex potential is also a valid complex potential in the zeta plane because phi and psi satisfy Laplace equation in both z and zeta planes and that is the whole idea of using zeta equal to f of z as a conformal transformation. So, what we have now come up with is that if we have a solution for some simple body, let us say in the z plane or zeta plane does not matter.

If the solution is available, which is in terms of phi and psi of course, then the solution to a more complex body can be obtained by just simply substituting zeta equal to f of z in the complex potential. So, we will take an example of this in the next lecture, but for now, let me talk about one aspect of this transformation, which is that how does the complex velocity transform, how does the complex velocity change due to this transformation.

So, recall that we defined complex velocity w as dF / dz where F is a complex potential. By chain rule I could write this as $dF / d\zeta \cdot d\zeta / dz$. Now, I note that F is a valid complex potential in both z and zeta planes because that is what we have derived now. So, $dF / d\zeta$

could be written as maybe complex velocity in the zeta plane that is dF/dz into $d\zeta/dz$. This is the complex velocity in the zeta plane.

So, what this equation tells us is that the complex velocities are proportional to each other. When you transform from one plane, let us say z plane to the zeta plane. So, they would be proportional with the constant of proportionality being the derivative $d\zeta/dz$. To show you how this works let us take an example.

(Refer Slide Time: 39:53)

$w(\zeta) = \frac{dF}{d\zeta} = \frac{dF}{dz} \frac{dz}{d\zeta}$ Complex velocity in ζ -plane.

EXAMPLE: Consider a uniform flow in ζ -plane
 Conformal transformation $\zeta = f(z) = z^2$
 $w(\zeta) = U$
 $\zeta = z^2 = (x+iy)^2 = x^2 - y^2 + 2ixy$
 $= \xi(x,y) + i\eta(x,y)$
 $\xi = x^2 - y^2$; $\eta = 2xy$
 $\frac{\partial \xi}{\partial x} = 2x$ $\frac{\partial \eta}{\partial x} = 2y$

$\frac{\partial \eta}{\partial x} = 2y$ $\frac{\partial \eta}{\partial y} = 2x$

$\zeta = z^2$ is a conformal transformation.

$w(z) = \frac{dF}{dz} = \frac{dF}{d\zeta} \frac{d\zeta}{dz} = U \cdot 2z = \underline{\underline{2Uz}}$

Let me take the example of the simplest possible velocity that we have encountered so far in this course. So, consider we have a uniform flow say in the zeta plane and we have a conformal transformation of the following type. So, the transformation is zeta is which is f of

z is z^2 . So, you want to calculate now that if you have a uniform flow in ζ plane what would it look like in the z plane.

So, clearly, this w in the ζ plane would be just U , say U is the magnitude of the uniform flow. So, w in ζ is U . Now, note that the transformation is $\zeta = z^2$, which could be written as $x^2 - y^2 + i2xy$, which would be $x^2 - y^2 + i2xy$ and which should be $\xi + i\eta$. So, clearly $\xi = x^2 - y^2$ and $\eta = 2xy$ for this transformation.

Now, if I take the derivative just to check whether this transformation satisfies the Cauchy Riemann equations, you can say $\frac{d\xi}{dx} = 2x$, we can say $\frac{d\eta}{dx} = 2y$ then $\frac{d\xi}{dy} = -2y$ and $\frac{d\eta}{dy} = 2x$. But do you notice that $\frac{d\xi}{dx} = \frac{d\eta}{dy}$ that is satisfied that is done and then you can say that $\frac{d\xi}{dy} = -\frac{d\eta}{dx}$. So, the Cauchy Riemann equations for this problem are satisfied and so, $\zeta = z^2$ is a conformal transformation.

So, it can be classified as a conformal transformation, because its components satisfy the Cauchy Riemann equations. Hence, we can now write that the complex velocity in the z plane would be $\frac{d\zeta}{dz}$ into the complex velocity in the ζ plane and the complex velocity in ζ plane has given us $U \frac{d\zeta}{dz} = 2z$. So, $w_z = 2Uz$. So, what we see in this example is that the complex velocity which was U in the ζ plane transforms to complex velocity in the z plane of the form $2Uz$, not just U .

And so, this is basically one way. This example shows us how these velocities will be transformed, we will come up with a conformal transformation. So, I will stop this lecture here. In the next lecture, we will finish up some remaining attributes of conformal transformation and that would basically also complete our discussion for this course. So, thank you.
